Getting generally intoxicated or drunk before going out and socializing or attending an event—called *pregaming*—has become a common practice among college students (Linden-Carmichael & Lau-Barraco, 2017; Meisel & others, 2018; Perrotte & others, 2018). One study revealed that almost two-thirds of students on one campus had pregamed at least once during a two-week period (DeJong, DeRicco, & Schneider, 2010). In a recent study, pregaming occurred more frequently when college women drank alcohol mixed with energy drinks (Linden-Carmichael & Lau-Barraco, 2017). Drinking games, in which the goal is to become intoxicated, also have become common on college campuses (Perrotte & others, 2018; Zamboanga & others, 2016, 2017). Higher levels of alcohol use have been consistently linked to higher rates of sexual risk taking, such as engaging in casual sex, having sex without using contraception, and committing sexual assaults (Bountress & others, 2017; Davies & others, 2017; Dvorak & others, 2016; Sutarso & others, 2018).

When does binge drinking peak during development? As shown in Figure 3, recent data from the *Monitoring the Future* study at the University of Michigan indicate that binge

#### BINGE DRINKING IN THE ADOLESCENCE-EARLY ADULTHOOD TRANSITION.

Note that the percentage of individuals engaging in binge drinking peaked at 21–22 years of age, remained high through the mid-twenties, then began to decline in the late twenties. Binge drinking was defined as having five or more alcoholic drinks in a row in the past two weeks.

Source: Schulenberg, J., et al. *Monitoring the Future*, Figure 4-20b, 2017.

drinking peaked at 21 to 22 years of age, with 38 percent in this age group reporting that they had engaged in binge drinking at least once in the last two weeks (Schulenberg & others, 2017).

**Alcoholism** *Alcoholism* is a disorder that involves long-term, repeated, uncontrolled, compulsive, and excessive use of alcoholic beverages and impairs the drinker's health and social relationships. A recent national study of more than 43,000 U.S. adults found that between 2001–2002 and 2012–2013, high-risk drinking and alcohol use disorder increased more in women, older adults, ethnic minorities, and individuals from low socioeconomic groups (Grant & others, 2017). One in nine individuals who drink will become an alcoholic. Those who do are disproportionately related to alcoholics (Gowin & others, 2017). Family studies consistently reveal a high frequency of alcoholism in the first-degree relatives of alcoholics (Lee & others, 2013).

Researchers have found a genetic influence on alcoholism (Enoch & others, 2016; Savage & others, 2018). An estimated 50 to 60 percent of individuals who become alcoholics are believed to have a genetic predisposition for it. Researchers also have documented that environmental factors play a role in alcoholism (Sun & others, 2016). For example, family studies indicate that many individuals who suffer from alcoholism do not have close relatives who are addicted to alcohol (McCutcheon & others, 2012). Large cultural variations in alcohol use also underscore the environment's role in alcoholism (Castro & others, 2015). For example, Orthodox Jews and Mormons have especially low rates of alcohol use and alcoholism.

About one-third of alcoholics recover, whether or not they are ever in a treatment program. This figure was found in a long-term study of 700 individuals over 50 years and has consistently been found by other researchers as well (Vaillant, 1992). There is a "one-third rule" for alcoholism: By age 65, one-third of alcoholics are dead or in terrible shape, one-third are abstinent or drinking socially, and one-third are still trying to beat their addiction.

**Cigarette Smoking and Nicotine** Converging evidence from a number of studies underscores the dangers of smoking or being around those who smoke (American Cancer Society, 2018). For example, smoking is linked to 30 percent of cancer deaths, 21 percent of heart disease deaths, and 82 percent of chronic pulmonary disease deaths. Secondhand smoke is implicated in as many as 9,000 lung cancer deaths a year. Children of smokers are at risk for a number of health problems, especially asthma (Hatoun & others, 2018; Rosen & others, 2018; Vo & others, 2017).

Fewer people smoke today than in the past, and almost half of all living adults who ever smoked have quit. In the United States, the prevalence of smoking in individuals 18 years of age and older dropped from 42 percent in 1965 to 18 percent (20 percent of males, 14.5 percent of females) in 2012, and then further to 15 percent in 2015 (Centers for Disease Control and Prevention, 2017). However, more than 50 million Americans still smoke cigarettes today. Cigarette smoking accounts for approximately 480,000 deaths, or 1 in 5 deaths, annually in the United States, including 41,000 deaths resulting from secondhand smoke exposure (Centers for Disease Control and Prevention, 2017). On average, smokers die 10 years earlier than nonsmokers.

Recently, just as there has been in adolescence, there has been a dramatic increase in use of e-cigarettes among individuals in emerging and early adulthood (Dutra & others, 2018; McCarthy, 2017; Pokhrel & others, 2018). In 2016, 8 percent of 19- to 22-year-olds used electronic vaporizers (which include e-cigarettes) in a 30-day period, then usage dropped to 7 percent at 23 to 24 years of age and further to 4 to 5 percent among 25- to 30-year-olds (Schulenberg & others, 2017). Recent research indicated that marijuana and alcohol use were risk factors for using e-cigarettes in emerging adulthood (Cohn & others, 2015). A recent study also found that emerging adults who used e-cigarettes were more likely to view emerging adulthood as a time of experimentation and were likely to experience such role transitions as loss of a job, dating someone new, and experiencing a romantic breakup (Allen & others, 2015).

Most adult smokers would like to quit, but their addiction to nicotine often makes quitting a challenge (Little & Ebbert, 2016; Raw & others, 2017). Nicotine, the active drug in cigarettes, is a stimulant that increases the smoker's energy and alertness, providing a

pleasurable and reinforcing experience (Yong & others, 2018). Nicotine also stimulates neurotransmitters (especially dopamine) that have a calming or pain-reducing effect (Nutt & others, 2015).

## 3 Sexuality

**LG3** Discuss sexuality in young adults.

Sexual Activity in Emerging Adulthood

Sexual Orientation and Behavior

Sexually Transmitted Infections

Forcible Sexual Behavior and Sexual Harassment

We do not need sex for everyday survival the way we need food and water, but we do need it for the survival of the species. We have examined how adolescents develop a sexual identity and become sexually active. What happens to their sexuality in early adulthood? Let's explore the sexual activity of Americans and their sexual orientation, as well as some of the problems that can be associated with sexual activity.

### SEXUAL ACTIVITY IN EMERGING ADULTHOOD

At the beginning of emerging adulthood (age 18), surveys indicate that slightly more than 60 percent of individuals have experienced sexual intercourse, but by the end of emerging adulthood (age 25), most individuals have had sexual intercourse (Lefkowitz & Gillen, 2006). Also, the U.S. average age for a first marriage has now climbed to 29.5 years for men and 27.4 years for women, higher than at any other point in history (Livingston, 2017). Thus, emerging adulthood is a time frame during which most individuals are both sexually active and unmarried.

Uncertainty characterizes many emerging adults' sexual relationships. Consider a study of emerging adult daters and cohabitators that found nearly half reported a reconciliation (a breakup followed by a reunion) (Halpern-Meekin & others, 2013). Also, one study of 18- to 26-year-olds revealed that perceived relationship commitment, though not formal relationship commitment (usually indexed by marriage), was linked to sexual enjoyment (Galinsky & Sonenstein, 2013).

A *sexual script* is a stereotyped pattern of role prescriptions for how individuals should behave sexually (Whitaker & others, 2018; Willie & others, 2018). In a recent research review, it was concluded that a sexual double standard continues to exist, with stricter social norms for female sexuality that include males being granted more sexual freedom and not being

criticized for having multiple sexual partners (Boislard, van de Bongardt, & Blais, 2016). One study explored heterosexual sexual scripts in focus groups with 18- to 26-year-old males and females (Sakaluk & others, 2014). The following sexual scripts were supported:

- *Sex Drive.* Men are always ready for sex; women inhibit their sexual expression.
- *Physical and Emotional Sex.* Men have a physical approach to sex; women have an emotional/relational approach to sex.
- *Sexual Performance.* Men and women should be sexually skilled and knowledgeable. One new aspect of this sexual script for women was agreement that women should especially have oral sex skills.
- *Initiation and Gateway Scripts.* Men initiate sex (most men and some women agreed with this script); women are gatekeepers (most men and women agreed that women set the sexual limits).
- *Sexual Evaluation.* Single women who appear sexual are judged negatively; men are rewarded for being sexual. However, there was negative judgment of men who come across as too sexual and too often engage in casual sex, especially with different women.

### developmental connection

#### Sexuality

Having intercourse in early adolescence is a risk factor in development. Connect to “Physical and Cognitive Development in Adolescence.”

Casual sex is more common in emerging adulthood than in the late twenties (Wesche & others, 2018). A recent trend has involved “hooking up” to have non-relationship sex (from kissing to intercourse) (Penhollow, Young, & Nnaka, 2017; Savage, Menegatos, & Roberto, 2017; Sullivan & others, 2018). One study revealed that 20 percent of first-year college women on one large university campus engaged in at least one hook-up over the course of the school year (Fielder & others, 2013). In this study, impulsivity, sensation seeking, and alcohol use were among the predictors of a higher likelihood of hooking up.

In addition to hooking up, another type of casual sex that has recently increased in emerging adults is “friends with benefits (FWB),” which involves a relationship formed by the integration of friendship and sexual intimacy without an explicit commitment characteristic of an exclusive romantic relationship (Weger, Cole, & Akbulut, 2018). A recent study found that suicidal ideation was associated with entrance into a friends-with-benefits relationship as well as continuation of the FWB relationship (Dube & others, 2017). Further, another recent study indicated that 40 percent of 22-year-olds reporting having had a recent casual sexual partner (Lyons & others, 2015). And a study of more than 3,900 18- to 25-year-olds revealed that having casual sex was negatively linked to well-being and positively related to psychological distress (Bersamin & others, 2014).

What are some predictors of risky heterosexual behavior in emerging adults, such as engaging in casual and unprotected sexual intercourse? Some research findings indicate the following (Lefkowitz & Gillen, 2006):

- Sexual risk factors increase in emerging adulthood, with males engaging in more of these risk factors than females (Willie & others, 2018). For example, males have more casual sexual partners while females report being more selective about their choice of a sexual partner.
- Individuals who become sexually active in adolescence engage in more risky sexual behaviors in emerging adulthood than do their counterparts who delay their sexual debuts until emerging adulthood.
- Emerging adults who are in college or who have graduated from college report having fewer casual sex partners than those without a high school diploma (Lyons & others, 2013).
- When emerging adults drink alcohol, they are more likely to have casual sex and less likely to discuss possible risks (Simons & others, 2018; Sutarso & others, 2018).

Approximately 60 percent of emerging adults have had sexual intercourse with only one individual in the past year, but compared with young adults in their late twenties and thirties, emerging adults are more likely to have had sexual intercourse with two or more individuals. Although emerging adults have sexual intercourse with more individuals than young adults do, they have sex less frequently. Approximately 25 percent of emerging adults report having sexual intercourse only a couple of times a year or not at all (Michael & others, 1994).

What are some characteristics of the sexual activity of emerging adults?

## SEXUAL ORIENTATION AND BEHAVIOR

A national study of sexual behavior in the United States among adults 25 to 44 years of age found that 98 percent of the women and 97 percent of the men said that they had ever engaged in vaginal intercourse (Chandra & others, 2011). Also in this study, 89 percent of the women and 90 percent of the men reported that they had ever had oral sex with an opposite-sex partner, and 36 percent of the women and 44 percent of the men stated that they had ever had anal sex with an opposite-sex partner.

Detailed information about various aspects of sexual activity in adults of different ages comes from the 1994 Sex in America survey. In this study Robert Michael and his colleagues (1994) interviewed more than 3,000 people from 18 to 59 years of age who were randomly selected, in sharp contrast with earlier samples that were based on unrepresentative groups of volunteers.

**Heterosexual Attitudes and Behavior** Here are some of the key findings from the 1994 Sex in America survey:

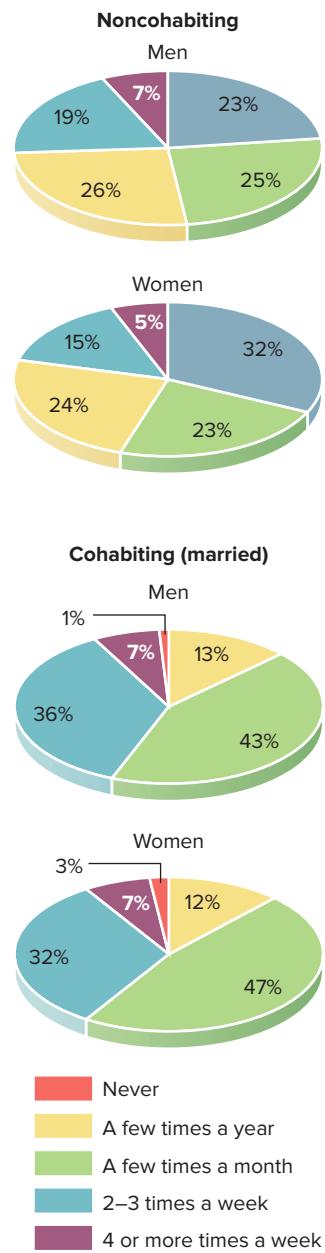

- Americans tend to fall into three categories: one-third have sex twice a week or more, one-third a few times a month, and one-third a few times a year or not at all.
- Married (and cohabiting) couples have sex more often than noncohabiting couples (see Figure 4).
- Most Americans do not engage in kinky sexual acts. When asked about their favorite sexual acts, the vast majority (96 percent) said that vaginal sex was “very” or “somewhat” appealing. Oral sex was in third place, after an activity that many have not labeled a sexual act—watching a partner undress.
- Adultery is clearly the exception rather than the rule. Nearly 75 percent of the married men and 85 percent of the married women indicated that they have never been unfaithful.
- Men think about sex far more often than women do—54 percent of the men said they think about it every day or several times a day, whereas 67 percent of the women said they think about it only a few times a week or a few times a month.

In sum, one of the most powerful messages in the 1994 survey was that Americans’ sexual lives are more conservative than was previously believed. Although 17 percent of the men and 3 percent of the women reported having had sex with at least 21 partners, the overall impression from the survey was that sexual behavior is ruled by marriage and monogamy for most Americans.

How extensive are gender differences in sexuality? A meta-analysis revealed that men reported having slightly more sexual experience and more permissive attitudes than women for most aspects of sexuality (Petersen & Hyde, 2010). For the following factors, stronger differences were found: Men indicated that they engaged more in masturbation, pornography use, and casual sex, and they held more permissive attitudes about casual sex than their female counterparts did. A more recent analysis (Sprecher, Treger, & Sakaluk, 2013) of almost 8,000 emerging adults found that males had stronger permissive attitudes, especially about sex in casual relationships, than the “slightly more” permissive attitudes in the meta-analysis (Petersen & Hyde, 2010) just described. In the more recent study, African American males had more permissive sexual attitudes than non-Latino White, Latino, and Asian males, while there were no ethnic differences found among females (Sprecher, Treger, & Sakaluk, 2013).

Given all of the media and public attention to the negative aspects of sexuality—such as adolescent pregnancy, sexually transmitted infections, rape, and so on—it is important to underscore that research has strongly supported the role of sexual activity in well-being (Brody, 2010; King, 2017, 2018). For example, in a Swedish study, frequency of sexual intercourse was strongly related to life satisfaction for both men and women (Brody & Costa, 2009). And in a recent study, sexual activity in adults on day 1 was linked to greater well-being the next day (Kashdan & others, 2018). Also in this study, higher levels of reported sexual pleasure and intimacy predicted more positive affect and less negative affect the next day.

**Sources of Sexual Orientation** In the Sex in America survey, 2.7 percent of the men and 1.3 percent of the women reported having had same-sex relations in the past year

**FIGURE 4**

**THE SEX IN AMERICA SURVEY.** The percentages show noncohabiting and cohabiting (married) males’ and females’ responses to the survey question “How often have you had sex in the past year?” (Michael & others, 1994). *What was one feature of the Sex in America survey that made it superior to most surveys of sexual behavior?*

Source: Michael, R. T., Gagnon, J. H., Laumann, E. O., & Kolata, G. *Sex in America*. Boston: Little, Brown, 1994.

What likely determines an individual's sexual orientation?

(Top to bottom) ©Laurence Mouton/Getty Images; ©2009 JupiterImages Corporation; ©2009 JupiterImages Corporation

(Michael & others, 1994). However, in a recent national survey a higher percentage (3.8 percent) of U.S. adults reported that they were gay, lesbian, bisexual, or transsexual (Gallup, 2015).

Why are some individuals lesbian, gay, or bisexual (LGB) and others heterosexual? Speculation about this question has been extensive (Crooks & Baur, 2017; King & Regan, 2019). Until the end of the nineteenth century, it was generally believed that people were either heterosexual or homosexual. Today, sexual orientation is generally seen not as an either/or proposition but as a continuum ranging from exclusive male-female relations to exclusive same-sex relations (King, 2017, 2018). Some individuals are bisexual, being sexually attracted to people of both sexes.

People sometimes think that bisexuality is simply a stepping-stone to homosexuality, while others view it as a sexual orientation itself or as an indicator of sexual fluidity (King, 2017, 2018). Evidence supports the notion that bisexuality is a stable orientation that involves attraction to both sexes (Lippa, 2013).

Compared with men, women are more likely to change their sexual patterns and desires (Knight & Hope, 2012). Women are more likely than men to have sexual experiences with same- and opposite-sex partners, even if they identify themselves strongly as being heterosexual or lesbian (King, 2017, 2018). Also, women are more likely than men to identify themselves as bisexual (Gates, 2011).

All people, regardless of their sexual orientation, have similar physiological responses during sexual arousal and seem to be aroused by the same types of tactile stimulation. Investigators typically find no differences between LGBs and heterosexuals in a wide range of attitudes, behaviors, and adjustments (Fingerhut & Peplau, 2013).

Recently, researchers have explored the possible biological basis of same-sex relations. The results of hormone studies have been inconsistent. If gays are given male sex hormones (androgens), their sexual orientation doesn't change. Their sexual desire merely increases. A very early prenatal critical period might influence sexual orientation (Hines, 2013). If this critical-period hypothesis turns out to be correct, it would explain why clinicians have found that sexual orientation is difficult, if not impossible, to modify.

An individual's sexual orientation—same-sex, heterosexual, or bisexual—is most likely determined by a combination of genetic, hormonal, cognitive, and environmental factors (Hyde & DeLamater, 2017; King, 2017, 2018). Most experts on same-sex relations point out that no single factor alone causes sexual orientation and that the relative weight of each factor can vary from one individual to the next.

Researchers have examined the role of genes in sexual orientation by using twins to estimate the genetic and environmental contributions to sexual orientation. A Swedish study of almost 4,000 twins demonstrated that only about 35 percent of the variation in homosexual behavior in men and 19 percent in women were explained by genetic differences (Langstrom & others, 2010). This result indicates that although genes likely play a role in sexual orientation, their influence is not as strong in explaining sexuality as it is for other characteristics such as intelligence (King, 2017, 2018). That said, it has become clear that whether they are heterosexual, gay, lesbian, or bisexual, people cannot be talked out of their sexual orientation (King, 2017).

**Attitudes and Behavior of Lesbians and Gays** Many gender differences that appear in heterosexual relationships also occur in same-sex relationships (Diamond & Alley, 2018; Savin-Williams, 2017, 2018). For example, like heterosexual women, lesbians have fewer sexual partners than gay men, and lesbians have less permissive attitudes about casual sex outside a primary relationship than gay men do (Fingerhut & Peplau, 2013).

A special concern involving sexual minority individuals are the hate crimes and stigma-related experiences they encounter (Baldwin & others, 2017; Conlin, Douglass, & Ouch, 2018; Douglass & others, 2017; Valdiserri & others, 2018). In one study, approximately 20 percent of sexual minority adults reported having experienced a person or property crime related to their sexual orientation, and about 50 percent said they had experienced verbal harassment (Herek, 2009).

## SEXUALLY TRANSMITTED INFECTIONS

**Sexually transmitted infections (STIs)** are diseases that are primarily spread through sexual contact—intercourse as well as oral-genital and anal-genital sex. STIs affect about one in six U.S. adults (National Center for Health Statistics, 2018). Among the most prevalent STIs are

STI	Description/cause	Incidence	Treatment
Gonorrhea	Commonly called the “drip” or “clap.” Caused by the bacterium <i>Neisseria gonorrhoeae</i> . Spread by contact between infected moist membranes (genital, oral-genital, or anal-genital) of two individuals. Characterized by discharge from penis or vagina and painful urination. Can lead to infertility.	500,000 cases annually in U.S.	Penicillin, other antibiotics
Syphilis	Caused by the bacterium <i>Treponema pallidum</i> . Characterized by the appearance of a sore where syphilis entered the body. The sore can be on the external genitals, vagina, or anus. Later, a skin rash breaks out on palms of hands and bottom of feet. If not treated, can eventually lead to paralysis or even death.	100,000 cases annually in U.S.	Penicillin
Chlamydia	A common STI named for the bacterium <i>Chlamydia trachomatis</i> , an organism that spreads by sexual contact and infects the genital organs of both sexes. A special concern is that females with chlamydia may become infertile. It is recommended that adolescent and young adult females have an annual screening for this STI.	About 3 million people in U.S. annually.	Antibiotics
Genital herpes	Caused by a family of viruses with different strains. Involves an eruption of sores and blisters. Spread by sexual contact.	One of five U.S. adults	No known cure but antiviral medications can shorten outbreaks
AIDS	Caused by a virus, the human immunodeficiency virus (HIV), which destroys the body's immune system. Semen and blood are the main vehicles of transmission. Common symptoms include fevers, night sweats, weight loss, chronic fatigue, and swollen lymph nodes.	More than 300,000 cumulative cases of HIV virus in U.S. 25–34-year-olds; epidemic incidence in sub-Saharan countries	New treatments have slowed the progression from HIV to AIDS; no cure
Genital warts	Caused by the human papillomavirus (HPV), which does not always produce symptoms. Usually appear as small, hard painless bumps in the vaginal area, or around the anus. Very contagious. Certain high-risk types of this virus cause cervical cancer and other genital cancers. May recur despite treatment. A new HPV preventive vaccine, Gardasil, has been approved for girls and women 9–26 years of age.	About 5.5 million new cases annually; considered the most common STI in the U.S.	A topical drug, freezing, or surgery

**FIGURE 5**  
**SEXUALLY TRANSMITTED INFECTIONS**

bacterial infections (such as gonorrhea, syphilis, and chlamydia) and STIs caused by viruses—genital herpes, genital warts, and HIV, which can lead to AIDS. Figure 5 describes several sexually transmitted infections.

No single STI has had a greater impact on sexual behavior, or created more public fear in the last several decades, than infection with the human immunodeficiency virus (HIV). HIV is a sexually transmitted infection that destroys the body's immune system. Once a person is infected with HIV, the virus breaks down and overpowers the immune system, which leads to acquired immune deficiency syndrome (AIDS). An individual sick with AIDS has such a weakened immune system that a common cold can be life-threatening.

In 2015, approximately 1.1 million people in the United States were living with an HIV infection (Centers for Disease Control and Prevention, 2017). In 2015, male-male sexual contact continued to be the most frequent AIDS transmission category.

Because of education and the development of more effective drug treatments, deaths due to HIV/AIDS have begun to decline in the United States (National Center for Health Statistics, 2018). To read about the background and work of one individual who counsels HIV/AIDS patients, see *Connecting with Careers*.

Globally, the total number of individuals living with HIV was 36.7 million in 2016, with 25.7 million of these individuals with HIV living in sub-Saharan Africa (UNAIDS, 2017). Currently, only about 60 percent of individuals with HIV know they have the disease (UNAIDS, 2017). Approximately half of all new HIV infections around the world occur in the 15- to 24-year-old age category. In one study, only 49 percent of 15- to 24-year-old females in low- and middle-income countries knew that using a condom helps to prevent HIV infection, compared with 74 percent of young males (UNAIDS, 2011). The good news is that global rates of HIV infection have fallen extensively since 2000 (UNAIDS, 2017).

### Pat Hawkins, Community Psychologist and Director of an HIV/AIDS Clinic

Pat Hawkins is the associate executive director for policy and external affairs of the Whitman-Walker Clinic in Washington, D.C., a facility that serves HIV and AIDS patients. She came to the clinic as a volunteer in 1983, just after HIV/AIDS exploded into an epidemic. Hawkins says that she would not do anything else but community work. "Nothing gets you engaged so fast as getting involved," she comments. "We often keep the academic world separate from the real world, and we desperately need psychologists' skills in the real world." Hawkins had a double major in psychology and sociology as an undergraduate and then went on to obtain her Ph.D. in community psychology.

Pat Hawkins counsels an AIDS patient.  
Courtesy of Dr. Patricia D. Hawkins

What are some effective strategies for protecting against HIV and other sexually transmitted infections? They include the following:

- *Know your risk status and that of your partner.* Anyone who has had previous sexual activity with another person might have contracted an STI without being aware of it. Spend time getting to know a prospective partner before you have sex. Use this time to inform the other person of your STI status and inquire about your partner's. Remember that many people lie about their STI status.
- *Obtain medical examinations.* Many experts recommend that couples who want to begin a sexual relationship have a medical checkup to rule out STIs before they engage in sex. If cost is an issue, contact your campus health service or a public health clinic.
- *Have protected, not unprotected, sex.* When used correctly, latex condoms help to prevent many STIs from being transmitted. Condoms are most effective in preventing gonorrhea, syphilis, chlamydia, and HIV. They are less effective against the spread of herpes.
- *Do not have sex with multiple partners.* One of the best predictors of getting an STI is having sex with multiple partners. Having more than one sex partner elevates the likelihood that you will encounter an infected partner.

## FORCIBLE SEXUAL BEHAVIOR AND SEXUAL HARASSMENT

Too often, sex involves the exercise of power. Here, we will briefly look at two of the problems that may result: rape and sexual harassment.

**Rape** Rape is forcible sexual intercourse with a person who does not give consent. Legal definitions of rape differ from state to state. For example, in some states husbands are not prohibited from forcing their wives to have intercourse, although this has been challenged in several of those states.

Because victims may be reluctant to suffer the consequences of reporting rape, the actual incidence is not easily determined (Littleton, Layh, & Rudolph, 2018). A recent meta-analysis found that 60 percent of rape victims do not acknowledge that they have been raped, with the percentage of unacknowledged rape especially high in college students (Wilson & Miller, 2016).

Nearly 200,000 rapes are reported each year in the United States. One study of college women who had been raped revealed that only 11.5 percent of them reported the rape to

**rape** Forcible sexual intercourse with a person who does not consent to it.

authorities, and of those for which the rape involved drugs and/or alcohol, only 2.7 percent of the rapes were reported (Wolitzky-Taylor & others, 2011).

Although most victims of rape are women, rape of men does occur (Casali & others, 2017). Men in prisons are especially vulnerable to rape, usually by heterosexual males who use rape as a means of establishing their dominance and power (Downer & Trestman, 2016).

Why does rape of women occur so often in the United States? Among the causes given are that males are socialized to be sexually aggressive, to regard women as inferior beings, and to view their own pleasure as the most important objective in sexual relations (Rudman, Fetterolf, & Sanchez, 2013; Vasquez & others, 2018). Researchers have found that male rapists share the following characteristics: aggression enhances their sense of power or masculinity; they are angry at women in general; and they want to hurt and humiliate their victims (Yarber, Sayad, & Strong, 2016). One study revealed that a higher level of men's sexual narcissism (assessed by these factors: sexual exploitation, sexual entitlement, low sexual empathy, and low sexual skill) was linked to a greater likelihood that they would engage in sexual aggression (Widman & McNulty, 2010). Rape is more likely to occur when one or both individuals are drinking alcohol (Brown, Horton, & Guillory, 2018). A recent study found that males and heavy drinkers are more likely to adhere to rape myths (such as women being held responsible for preventing the rape) than females or people who drink little or no alcohol (Hayes, Abbott, & Cook, 2016).

Rape is a traumatic experience for the victims and those close to them (Gray, Hassija, & Steinmetz, 2017). As victims strive to get their lives back to normal, they may experience depression, fear, anxiety, posttraumatic stress disorder, increased substance use, and suicidal thoughts for months or years (Bovin, Wolf, & Resick, 2017; Dworkin & others, 2018; Londono, 2017). Many victims make changes in their lives—such as moving to a new apartment or refusing to go out at night. Recovery depends on the victim's coping abilities, psychological adjustment prior to the assault, and social support (Gray, Hassija, & Steinmetz, 2017). Parents, a partner, and others close to the victim can provide important support for recovery, as can mental health professionals.

An increasing concern is **date or acquaintance rape**, which is coercive sexual activity directed at someone with whom the perpetrator is at least casually acquainted (Angelone, Mitchell, & Smith, 2018; Miller, 2017). In one survey, two-thirds of female college freshmen reported having been date raped or having experienced an attempted date rape at least once (Watts & Zimmerman, 2002). About two-thirds of college men admit that they fondle women against their will, and half admit to forcing sexual activity. In a recent study of 1,423 four-year universities, those with higher tuition, more liquor violations, and greater numbers of fraternity men and athletes were more likely to report rape on their campuses (Wiersma-Mosley, Jozkowski, & Martinez, 2017).

A number of colleges and universities have identified a “red zone” among female students—a period of time early in the first year of college when women are at especially high risk for unwanted sexual experiences (Gray, Hassija, & Steinmetz, 2017). One study revealed that first-year women were at higher risk for unwanted sexual experiences, especially early in the fall term, than second-year women (Kimble & others, 2008). Exactly how prevalent are sexual assaults on college campuses? To find out, see *Connecting Through Research*.

**Sexual Harassment** Sexual harassment is a manifestation of power of one person over another. It takes many forms, ranging from inappropriate sexual remarks and physical contact (patting, brushing against another person's body) to blatant propositions and sexual assaults. Millions of women experience sexual harassment each year in work and educational settings (Fitzgerald, 2017; Shakil, Lockwood, & Gradey, 2018; Walsh & Gates, 2018). Sexual harassment of men by women also occurs but to a far lesser extent than sexual harassment of women by men. In 2017, the Me Too Movement spread extensively with “Me Too” (or “#MeToo”)

What are some characteristics of acquaintance rape in colleges and universities?

**date or acquaintance rape** Coercive sexual activity directed at someone with whom the perpetrator is at least casually acquainted.

## How Prevalent Are Sexual Assaults on College Campuses?

A major study that focused on campus sexual assault involved a phone survey of 4,446 women attending two- or four-year colleges (Fisher, Cullen, & Turner, 2000). Sexual victimization was measured in a two-stage process. First, a series of screening questions were asked to determine whether the respondent had experienced an act that might possibly be a victimization. Second, if the respondent answered "yes," she was asked detailed questions about the incident, such as the type of unwanted contact and the means of coercion. In addition, respondents were asked about other aspects of their lives, including their lifestyles, routine activities, living arrangements, and prior sexual victimization.

Slightly less than 3 percent said that they had experienced either a rape or an attempted rape during the current academic year. About 1 in 10 college women said that they had experienced rape in their lifetime. Unwanted or uninvited sexual contacts were widespread, with more than one-third of the college women reporting these incidents. As shown in Figure 6, in this study, most women (about 9 out of 10) knew the person who had sexually victimized them. Most of the women attempted to take protective actions against their assailants but were reluctant to report the victimization to the police for a number of reasons (such as embarrassment, not clearly understanding the legal definition of rape, or not wanting to define someone they knew who had victimized them as a rapist). Several factors were associated with sexual victimization: living on campus, being unmarried, getting drunk frequently, and experiencing prior sexual victimization. The majority of rapes occurred in living quarters.

In addition, the researchers in this study examined a form of sexual victimization that has been studied infrequently: stalking. Thirteen percent of the female students said they had been stalked since the school year began. As with other sexual victimizations, 80 percent knew their stalkers, who most often were boyfriends (42 percent) or classmates (24 percent). Stalking incidents lasted an average of 60 days.

**FIGURE 6**

### RELATIONSHIP BETWEEN VICTIM AND OFFENDER IN COMPLETED AND ATTEMPTED RAPES OF COLLEGE WOMEN.

In a phone survey of college women, slightly less than 3 percent of the women said they had experienced a rape or attempted rape during the academic year (Fisher, Cullen, & Turner, 2000). The percentages shown here indicate the relationship between the victim and the offender. *What were some possible advantages and disadvantages of using a phone survey rather than face-to-face interviews to conduct this study?*

Source: Fisher, B. S., Cullen, F. T., & Turner, M. G. *The sexual victimization of college women*. Washington, DC: National Institute of Justice, 2000.

Given the prevalence of sexual assault on college campuses and the frequency with which those assaults involve perpetrators the victims know, it is clear that more research needs to be dedicated to identifying effective intervention strategies for young men and women. In the past, too often the responsibility of prevention was placed on the would-be victim's behavior. While those sorts of strategies are not unhelpful, prevention strategies that target the behavior of the would-be rapist might get closer to the root of the problem.

What are some factors that likely led to the Me Too Movement?

©FS2/FayesVision/WENN/Newscom

used as a hashtag on social media to show the prevalence of sexual assault and harassment of women, especially in the workplace. Many women who previously had remained silent about being sexually harassed came forward and openly discussed their experience.

In a survey of 2,000 college women, 62 percent reported having experienced sexual harassment while attending college (American Association of University Women, 2006). Most of the college women said that the sexual harassment involved noncontact forms such as crude jokes, remarks, and gestures. However, almost one-third said that the sexual harassment was physical in nature. Sexual harassment can result in serious psychological consequences for the victim. The elimination of this type of exploitation requires the establishment of work and academic environments that provide women and men with equal opportunities to develop a career and obtain an education in a climate free of sexual harassment (Nielsen & others, 2017; Wolf, Rospenda, & Colaneri, 2017).

## Review Connect Reflect

**LG3** Discuss sexuality in young adults.

### Review

- What characterizes the sexual activity of emerging adults?
- What is the nature of heterosexuality and same-sex sexual orientation?
- What are sexually transmitted infections? What are some important things to know about AIDS?
- What is rape? What is date or acquaintance rape? What are the effects of forcible sexual behavior and sexual harassment?

### Connect

- As you learned in this section, sexual assault is connected with aggression

in males. In the chapter entitled "Socioemotional Development in Early Childhood," what was identified as one way in which children learn to behave aggressively?

### Reflect Your Own Personal Journey of Life

- How would you describe your sexual experiences during emerging adulthood? How similar or dissimilar are they to the way sexuality in emerging adulthood was described in this section?

## 4 Cognitive Development

**LG4**

Characterize cognitive changes in early adulthood.

Cognitive Stages

Creativity

Are there changes in cognitive performance during early adulthood? To explore the nature of cognition during this period of development, we will focus on issues related to cognitive stages and creative thinking.

### COGNITIVE STAGES

Are young adults more advanced in their thinking than adolescents are? Let's examine how Jean Piaget and others have answered this intriguing question.

**Piaget's View** Piaget concluded that an adolescent and an adult think in the same way qualitatively. That is, Piaget argued that at approximately 11 to 15 years of age, adolescents enter the formal operational stage, which is characterized by more logical, abstract, and idealistic thinking than the concrete operational thinking of 7- to 11-year-olds. Piaget did stress that young adults are more quantitatively advanced in their thinking in the sense that they have more knowledge than adolescents. He also reasoned, as do information-processing psychologists, that adults especially increase their knowledge in a specific area, such as a physicist's understanding of physics or a financial analyst's knowledge of finance. According to Piaget, however, formal operational thought is the final stage in cognitive development, and it characterizes adults as well as adolescents.

Some developmentalists theorize it is not until adulthood that many individuals consolidate their formal operational thinking. That is, they may begin to plan and hypothesize about intellectual problems in adolescence, but they become more systematic and sophisticated at this process as young adults. Nonetheless, even many adults do not think in formal operational ways (Keating, 2004).

**Is There a Fifth, Postformal Stage?** Some theorists have pieced together these descriptions of adult thinking and have proposed that young adults move into a new qualitative stage of cognitive development, postformal thought (Sinnott, 2003).

**Postformal thought** is:

- *Reflective, relativistic, and contextual.* As young adults engage in solving problems, they might think deeply about many aspects of work, politics, relationships, and other areas of life (Labouvie-Vief, 1986). They find that what might be the best solution to a problem at

### developmental connection

#### Cognitive Theory

Adolescent cognition also includes adolescent egocentrism. Connect to "Physical and Cognitive Development in Adolescence."

**postformal thought** Thinking that is reflective, relativistic, contextual, provisional, realistic, and influenced by emotions.

## developmental connection

### Cognitive Theory

Links between cognition and emotion are increasingly being studied. Connect to “Introduction.”

What are some ways that young adults might think differently from adolescents?

©Shutterstock/wavebreakmedia

work (with a boss or co-worker) might not be the best solution at home (with a romantic partner). Thus, postformal thought holds that the correct solution to a problem requires reflective thinking and may vary from one situation to another. Some psychologists argue that reflective thinking continues to increase and becomes more internal and less contextual in middle age (Labouvie-Vief, Gruhn, & Studer, 2010; Mascalo & Fischer, 2010).

- *Provisional.* Many young adults also become more skeptical about the truth and seem unwilling to accept an answer as final. Thus, they come to see the search for truth as an ongoing and perhaps never-ending process.
- *Realistic.* Young adults understand that thinking can't always be abstract. In many instances, it must be realistic and pragmatic.
- *Recognized as being influenced by emotion.* Emerging and young adults are more likely than adolescents to understand that their thinking is influenced by emotions (Girgis & others, 2018; Labouvie-Vief, Gruhn, & Studer, 2010). However, too often negative emotions produce thinking that is distorted and self-serving at this point in development.

How strong is the evidence for a fifth, postformal stage of cognitive development? Researchers have found that young adults are more likely to engage in postformal thinking than adolescents are (Commons & Bresette, 2006). But critics argue that research has yet to document that postformal thought is a qualitatively more advanced stage than formal operational thought.

In addition to the characteristics just described for a possible fifth, postformal stage, a recent study explored wisdom and meaning as important developments in emerging adulthood (Webster & others, 2018). In this study, it was found that the search for and presence of meaning was linked to wisdom, which was assessed with five components: critical life experiences, reminiscence/reflectiveness, openness to experience, emotional regulation, and humor. We will further explore meaning in life in the chapter on “Socioemotional Development in Middle Adulthood” and wisdom in the chapter on “Cognitive Development in Late Adulthood.”

## CREATIVITY

At the age of 30, Thomas Edison invented the phonograph, Hans Christian Andersen wrote his first volume of fairy tales, and Mozart composed *The Marriage of Figaro*. One early study of creativity found that individuals' most creative products were generated in their thirties and that 80 percent of the most important creative contributions were completed by age 50 (Lehman, 1960). More recently, researchers have found that creativity peaks in adulthood and then declines, but the peak often occurs in the forties. However, qualifying any conclusion about age and creative accomplishments are (1) questions about the magnitude of the decline in productivity, (2) contrasts across creative domains, and (3) individual differences in lifetime output (Simonton, 1996).

Even though a decline in creative contributions is often found in the fifties and later, the decline is not as great as is commonly thought. An impressive array of creative accomplishments can occur in late adulthood. One of the most remarkable examples of creative accomplishment in late adulthood is the life of Henri Chevreul. After a distinguished career as a physicist, Chevreul switched fields in his nineties to become a pioneer in gerontological research. He published his last research paper just a year prior to his death at the age of 103!

Any consideration of decline in creativity with age requires attention to the field of creativity involved (Kozbelt, 2014; McKay & Kaufman, 2014). In such fields as philosophy and history, older adults often show as much creativity as they did when they were in their thirties and forties. By contrast, in such fields as lyrical poetry, abstract math, and theoretical physics, the peak of creativity is often reached in the twenties or thirties.

There also is extensive individual variation in the lifetime output of creative individuals (Kandler & others, 2016). Typically, the most productive creators in any field are far more prolific than their least productive counterparts. The top 10 percent of creative producers often account for 50 percent of the creative output in a particular field. For instance, only 16 composers account for half of the music regularly performed in the classical repertoire.

Researchers have found that personality traits are linked to creativity (Feist, 2018; Kandler & others, 2016). In one recent study, the personality trait of openness to experience predicted creativity in the arts, while intellect predicted creativity in the sciences (Kaufman & others, 2016). See *Connecting Development to Life* for strategies for becoming more creative.

## Flow and Other Strategies for Living a More Creative Life

Mihaly Csikszentmihalyi (pronounced ME-high CHICK-sent-me-high-ee) has studied the nature of creativity and recommends a number of strategies for becoming more creative (Csikszentmihalyi, 1995, 2014, 2018). In one project, Csikszentmihalyi (1995) interviewed 90 leading figures in art, business, government, education, and science to learn how creativity works. He discovered that creative people regularly experience a state he calls flow, a heightened state of pleasure experienced when we are engaged in mental and physical challenges that absorb us. Csikszentmihalyi (2000) points out that everyone is capable of achieving flow. Based on his interviews with some of the most creative people in the world, the first step toward a more creative life is cultivating your curiosity and interest. How can you do this? Here are some ideas:

- *Try to be surprised by something every day.* It may be something you see, hear, or read about. Become absorbed in a lecture or a book. Be open to what the world is telling you.
- *Try to surprise at least one person every day.* In a lot of things you do, you have to be predictable and patterned. Do something different for a change. Ask a question you normally would not ask. Invite someone to go to a show or a museum you never have visited.
- *Write down each day what surprised you and how you surprised others.* Most creative people keep a diary or notes to ensure that their experience is not fleeting or forgotten. Start with a specific task. Each evening record the most surprising event that occurred that day and your

Mihaly Csikszentmihalyi, in the setting where he gets his most creative ideas. *When and where do you get your most creative thoughts?*  
Courtesy of Dr. Mihaly Csikszentmihalyi

most surprising action. After a few days, reread your notes and reflect on your past experiences. After a few weeks, you might see a pattern of interest emerging in your notes, one that might suggest an area you can explore in greater depth.

- *When something sparks your interest, follow it.* Usually when something captures your attention, it is short-lived—an idea, a song, a flower. Too often we are too busy to explore these further. Or we think these areas are none of our business because we are not experts about them. Yet the world is our business. We can't know which part of it is best suited to our interests until we make a serious effort to learn as much about as many aspects of it as possible.

most surprising action. After a few days, reread your notes and reflect on your past experiences. After a few weeks, you might see a pattern of interest emerging in your notes, one that might suggest an area you can explore in greater depth.

- *Wake up in the morning with a specific goal to look forward to.* Creative people wake up eager to start the day, not necessarily because they are cheerful, enthusiastic types but because they know that there is something meaningful to accomplish each day, and they can't wait to get started.

most surprising action. After a few days, reread your notes and reflect on your past experiences. After a few weeks, you might see a pattern of interest emerging in your notes, one that might suggest an area you can explore in greater depth.

- *Spend time in settings that stimulate your creativity.* In Csikszentmihalyi's (1995) research, he gave people an electronic pager and beeped them randomly at different times of the day. When he asked them how they felt, they reported the highest levels of creativity when walking, driving, or swimming. I (your author)

do my most creative thinking when I'm jogging. These activities

are semiautomatic in that they take a certain amount of attention

while leaving some time free to make connections among ideas.

Can the strategies for stimulating creative thinking in children also be used by adults? How do the strategies discussed in the chapter entitled "Physical and Cognitive Development in Middle and Late Childhood" compare with those discussed here?

### Review Connect Reflect

**LG4** Characterize cognitive changes in early adulthood.

#### Review

- What changes in cognitive development in young adults have been proposed?
- Does creativity decline in adulthood? How can people lead more creative lives?

#### Connect

- Postformal thought is characterized in part by an understanding that emotions and subjective factors influence thinking. Why are

adolescents not typically capable of this kind of awareness?

#### Reflect Your Own Personal Journey of Life

- If you are in emerging adulthood, what do you think are the most important cognitive changes that have taken place so far in the transition period? If you are older, reflect on your emerging adult years and describe some of the cognitive changes that occurred during this time.

## 5 Careers and Work

LG5 Explain the key dimensions of career and work in early adulthood.

Developmental Changes

Finding a Path to Purpose

Monitoring the Occupational Outlook

The Impact of Work

Diversity in the Workplace

Earning a living, choosing an occupation, establishing a career, and developing in a career—these are important themes of early adulthood. What are some of the factors that go into choosing a job or career, and how does work typically affect the lives of young adults?

### DEVELOPMENTAL CHANGES

Many young children have idealistic fantasies about what they want to be when they grow up, such as superheroes, sports stars, or movie actors. In the high school years, they begin to think about careers from a somewhat less idealistic perspective. In their late teens and early twenties, their career decision making has usually turned more serious as they explore different career possibilities and zero in on the career they want to enter. In college, this often means choosing a major or specialization that is designed to lead to work in a particular field. By their early and mid-twenties, many individuals have completed their education or training and entered a full-time occupation. From the mid-twenties through the remainder of early adulthood, individuals often seek to establish their emerging career in a particular field, working hard to move up the career ladder and improve their financial standing.

Phyllis Moen (2009a) described the career mystique—an ingrained cultural belief that engaging in hard work for long hours through adulthood will lead to status, security, and happiness. That is, many individuals envision a career path that will enable them to fulfill the American dream of upward mobility by climbing occupational ladders. However, the lockstep career mystique has never been a reality for many individuals, especially ethnic minority individuals, women, and poorly educated adults. Further, the career mystique has increasingly become a myth for many individuals in middle-income occupations as global outsourcing of jobs, rapid technological change, and the long-term effects of the 2007–2009 recession have threatened the job security of millions of Americans.

### FINDING A PATH TO PURPOSE

William Damon (2008) proposed in his book *The Path to Purpose: Helping Our Children Find Their Calling in Life* that purpose is a missing ingredient in many adolescents' and emerging adults' achievement and career development. Too many youth drift aimlessly through their high school and college years, Damon says, engaging in behavior that places them at risk for not fulfilling their potential and not finding a life pursuit that energizes them.

In interviews with 12- to 22-year-olds, Damon found that only about 20 percent had a clear vision of where they wanted to go in life, what they wanted to achieve, and why. The largest percentage—about 60 percent—had engaged in some potentially purposeful activities, such as service learning or fruitful discussions with a career counselor—but they still did not have a real commitment or any reasonable plans for reaching their goals. And slightly more than 20 percent expressed no aspirations and in some instances said they didn't see any reason to have aspirations.

Damon concludes that most teachers and parents communicate the importance of studying hard and getting good grades, but rarely discuss the purpose of academic achievement. Damon emphasizes that too often students focus only on short-term goals and don't explore the big, long-term picture of what they want to do in life. The following interview questions that Damon (2008, p. 135) has used in his research are good springboards for getting individuals to reflect on their purpose:

- What's most important to you in your life?
- Why do you care about those things?
- Do you have any long-term goals?

- Why are these goals important to you?
- What does it mean to have a good life?
- What does it mean to be a good person?
- If you were looking back on your life now, how would you like to be remembered?

Recent research has provided support for the importance of purpose in people's lives. In one study, purpose predicted emerging adults' well-being (Hill & others, 2016). In another study, a high sense of purpose in life was associated with a lower incidence of cardiovascular disease and living a longer life (Cohen, Bavishi, & Rozanski, 2016).

## MONITORING THE OCCUPATIONAL OUTLOOK

As you explore the type of work you are likely to enjoy and in which you can succeed, keep in mind that occupations may have many job openings one year but few in another year as economic conditions change. Thus, it is critical to keep up with the occupational outlook in various fields. An excellent source for doing this is the U.S. government's *Occupational Outlook Handbook*, which is revised every two years. According to the 2016–2017 handbook, wind turbine service technicians, occupational therapy assistants, physical therapist assistants, physical therapist aides, home health aides, commercial drivers, nurse practitioners, physical therapists, and statisticians are among the job categories that are projected to be the fastest-growing through 2024. Projected job growth varies widely by educational requirements. Jobs that require a college degree are expected to grow the fastest. Most of the highest-paying occupations require a college degree. To read about the work of one individual who advises about careers, see the *Connecting with Careers* profile of Grace Leaf earlier in this chapter.

Hari Prabhakar (*in rear*) at a screening camp in India that he created as part of his Tribal India Health Foundation. Hari reflects William Damon's concept of finding a path to purpose. His ambition is to become an international health expert. A 2006 graduate from Johns Hopkins University (with a double major in public health and writing) and a top student (3.9 GPA), he took the initiative to pursue a number of activities outside the classroom, in the health field. As he made the transition from high school to college, Hari created the Tribal India Health Foundation ([www.tihf.org](http://www.tihf.org)), which provides assistance in bringing low-cost health care to rural areas in India. Juggling roles as a student and as the foundation's director, Hari spent about 15 hours a week leading Tribal India Health throughout his four undergraduate years. In describing his work, Hari said (Johns Hopkins University, 2006): "I have found it very challenging to coordinate the international operation. . . . It takes a lot of work, and there's not a lot of free time. But it's worth it when I visit our patients and see how they and the community are getting better."

Courtesy of Hari Prabhakar

## THE IMPACT OF WORK

Work defines people in fundamental ways (Adler & Elmhurst, 2019; Hsieh & Huang, 2017). It influences their financial standing, housing, the way they spend their time, where they live, their friendships, and their health (Blustein, 2013). Some people define their identity through their work. Work also creates a structure and rhythm to life that is often missed when individuals do not work for an extended period. Many individuals experience emotional distress and low self-esteem when they are unable to work.

Most individuals spend about one-third of their time at work. In one survey, U.S. individuals 18+ years old who were employed full-time were working an average of 47 hours per week, almost a full work day longer than the standard 9-to-5, Monday-through-Friday schedule (Saad, 2014). In this survey, half of all individuals working full-time reported that they work more than 40 hours a week and nearly 40 percent said they work 50 hours a week or more. Only 8 percent indicated they worked less than 40 hours per week.

The U.S. job market for college graduates has been improving recently. According to a recent survey, 74 percent of employers reported that they were planning to hire recent college graduates in 2017, up from 67 percent in 2016 (CareerBuilder, 2017). The 74 percent figure is the best job outlook for recent college graduates since 2007. Also good news for recent college graduates is that in 2017, employers said they were planning to pay new college graduates more than they did in 2016.

A trend in the U.S. workforce is the disappearing long-term career for an increasing number of adults, especially men in private-sector jobs (Hollister, 2011). Among the reasons is the dramatic increase in technology and availability of cheaper labor in other countries. Many young and older adults are working at a series of jobs that often last for a short time (Greenhaus & Callanan, 2013). Early careers are especially unstable as some young workers move from "survival jobs" to "career jobs" while seeking a job that matches their personal interests and goals (Staff, Mont'Alvao, & Mortimer, 2015). A study of 1,100 individuals from

### developmental connection

#### Work

The middle-aged worker faces a number of challenges in the twenty-first century. Connect to "Physical and Cognitive Development in Middle Adulthood."

What are some characteristics of work settings linked with employees' stress?

©Creativa Images/Shutterstock

18 to 31 years of age revealed that maintaining a high aspiration and certainty over career goals better insulated individuals against unemployment in the severe economic recession that began in 2007 (Vuolo, Staff, & Mortimer, 2012).

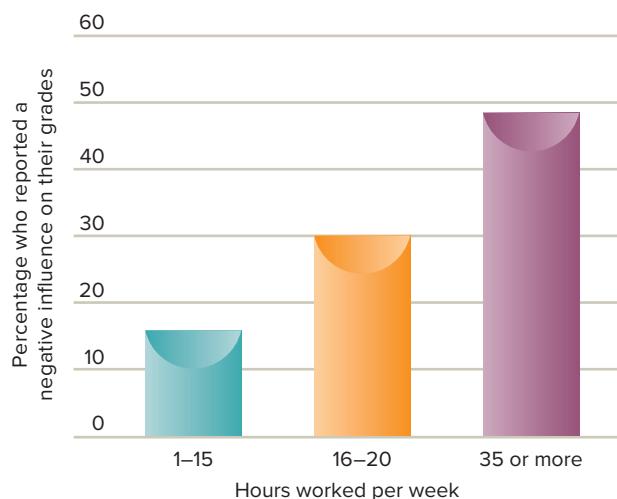

An important consideration regarding work is how stressful it is (Dragano & others, 2017; Hassard & others, 2017; Mayerl & others, 2017). A national survey of U.S. adults revealed that 55 percent indicated that stress prevented them from being as productive as they wanted to be (American Psychological Association, 2007). In this study, 52 percent reported that they considered or made a career decision, such as looking for a new job, declining a promotion, or quitting a job, because of stress in the workplace (American Psychological Association, 2007). In this survey, main sources of stress included low salaries (44 percent), lack of advancement opportunities (42 percent), uncertain job expectations (40 percent), and long hours (39 percent). One study revealed that stressors at work were linked to arterial hypertension in employees (Lamy & others, 2014). Another recent study indicated that an increase in job strain increased workers' insomnia, while a decrease in job strain reduced their insomnia (Halonen & others, 2018).

Many adults have changing expectations about work, yet employers often aren't meeting their expectations (Hall & Mirvis, 2013). For example, current policies and practices were designed for male breadwinners and an industrial economy, making these policies and practices out of step with a workforce of women and men, and of single-parent and dual earners. Many workers today want flexibility and greater control over their work schedules, yet most employers offer little flexibility, even though policies like flextime may be "on the books."

**Work During College** The percentage of full-time U.S. college students who also held jobs increased from 34 percent in 1970 to 47 percent in 2008, then declined to 43 percent in 2015 (down from a peak of 52 percent in 2000) (National Center for Education Statistics, 2017). In 2015, 78 percent of part-time U.S. college students were employed, up from 74 percent in 2011 but slightly down from 81 percent in 2008.

Working can offset some of the costs of schooling, but it also can restrict learning opportunities. For those who identified themselves primarily as students, one study found that as the number of hours worked per week increased, their grades suffered (National Center for Education Statistics, 2002) (see Figure 7). Students need to examine whether the number of hours they work is having a negative impact on their college success.

Of course, jobs also can enhance your education. More than 1,000 colleges in the United States offer *cooperative (co-op) programs*, which are paid apprenticeships in a field that you are interested in pursuing. (You may not be permitted to participate in a co-op program until your junior year.) Other useful opportunities for working while going to college include internships and part-time or summer jobs relevant to your field of study. Participating in these work experiences can help you land the job you want after you graduate.

**FIGURE 7**

**THE RELATION OF HOURS WORKED PER WEEK IN COLLEGE TO GRADES.**

Among students working to pay for school expenses, 16 percent of those working 1 to 15 hours per week reported that working negatively influenced their grades (National Center for Education Statistics, 2002). Thirty percent of college students who worked 16 to 20 hours a week said the same, as did 48 percent who worked 35 hours or more per week. Source: National Center for Education Statistics (2002). *Work during college*. Washington, DC: U.S. Office of Education.

**Unemployment** Unemployment rates in the United States have remained high in recent years, and global unemployment is increasing. Unemployment produces stress regardless of whether the job loss is temporary, cyclical, or permanent (Frasquilho & others, 2016; Jalles & Andresen, 2014). In a recent study, depression following job loss predicted increased risk of continued unemployment (Stolove, Galatzer-Levy, & Bonanno, 2017). Researchers have found that unemployment is related to physical problems (such as heart attack and stroke), emotional problems (such as depression and anxiety), marital difficulties, and homicide (Rizvi & others, 2015; Yoo & others, 2016). Another study revealed that 90 or more days of unemployment was associated with subsequent cardiovascular disease across an 8-year follow-up period (Lundin & others, 2014). In one study, unemployment was associated with higher rates of tobacco and illicit drug use, as well as heavy alcohol use (Compton & others, 2014). A 15-year longitudinal study of more than 24,000 adults found that their life satisfaction dropped considerably during unemployment and increased after they became reemployed but did not completely return to their life satisfaction level prior to being unemployed (Lucas & others, 2004). A research review concluded that unemployment was associated with an increased mortality risk for individuals in the early

and middle stages of their careers, but the increase was less pronounced for those who became unemployed late in their careers (Roelfs & others, 2011). Also, in a recent study, depression following job loss predicted increased risk of continued unemployment (Stolove & others, 2017). Another study found that involuntary job loss was linked to an increase in attempted suicide and suicide (Milner & others, 2014).

Might unemployment be linked to certain characteristics in childhood? Longitudinal data revealed that low self-control in childhood was linked to the emergence and persistence of unemployment from 21 to 50 years of age (Daly & others, 2015). Further, a recent study found that heavy drinking from 16 to 30 years of age was linked to higher unemployment in middle age (Berg & others, 2018).

Stress caused by unemployment comes not only from a loss of income and the resulting financial hardships but also from decreased self-esteem (Howe & others, 2012). Individuals who cope best with unemployment have financial resources to rely on, often savings or the earnings of other family members. The support of understanding, adaptable family members also helps individuals cope with unemployment. Job counseling and self-help groups can provide emotional support during the job search as well as practical advice on finding job opportunities, writing résumés, and answering questions in job interviews (van Hooft, 2014).

**Dual-Earner Couples** Dual-earner couples may face special challenges finding a balance between work and family life (Aazami, Shamsuddin, & Akmal, 2015; Schooreel & Verbruggen, 2016). If both partners are working, who takes care of the seemingly endless details involved in maintaining a home? If the couple has children, who is responsible for making sure that the children get to school, who fills out field trip forms, and who makes the dental appointments?

Although single-earner married families make up a sizeable minority of families, the proportion of two-earner couples has increased considerably. As more U.S. women took jobs outside the home, the division of responsibility for work and family changed in three ways: (1) men began taking more responsibility for maintaining the home; (2) women began taking more responsibility for breadwinning; (3) men began to show greater interest in their families and parenting.

Many jobs have been designed for single earners, usually male breadwinners, without regard to family responsibilities or the realities of people's lives (Richardson & Schaeffer, 2013). Consequently, many dual-earner couples engage in a range of adaptive strategies to coordinate their work and manage the family side of the work-family equation (Flood & Genadek, 2016; Moen, 2009a, b; Sun & others, 2017; Wang & Repetti, 2014). Researchers have found that even though couples may strive for gender equality in dual-earner families, gender inequalities persist (Cunningham, 2009). For example, women still do not earn as much as men in the same jobs, and this inequity leads to ongoing gender divisions in how much time each partner spends in paid work, homemaking, and caring for children. Thus, dual-earner career decisions often are made in favor of men's greater earning power, with women spending more time than men taking care of the home and caring for children (Moen, 2009b). One study indicated that women reported more family interference from work than did men (Allen & Finkelstein, 2014). Another recent study found that partner coping, having a positive attitude toward multiple roles, using planning and management skills, and not having to cut back on professional responsibilities were linked to better relationships between dual earners (Matias & Fontaine, 2015).

*How has the diversity of the workplace increased in recent years?*

©Ryan McVay/Getty Images

## DIVERSITY IN THE WORKPLACE

The workplace is becoming increasingly diverse (Adler & Elmhurst, 2019; Hsieth & Huang, 2018). Whereas at one time few women were employed outside the home, in developed countries women have increasingly entered the labor force. A recent projection indicates that women's share of the U.S. labor force will increase faster than men's share through 2024 (Occupational Outlook Handbook, 2016/2017). In the United States, more than one-fourth of today's lawyers, physicians, computer scientists, and chemists are women.

Ethnic diversity also is increasing in the workplace in every developed country except France. In the United States, between 1980 and 2004 the percentage of Latinos and Asian Americans more than doubled in the workplace, a trend that is continuing (Occupational Outlook Handbook, 2016/2017). Latinos are projected to

constitute a larger percentage of the labor force, growing 25 percent from 2014 to 2024, as are Asian Americans, growing 21 percent from 2014 to 2024 (Occupational Outlook Handbook, 2016/2017). The increasing diversity in the workplace requires a sensitivity to cultural differences and an appreciation of the cultural values that workers bring to a job (Ebert & Griffin, 2019).

Despite the increasing diversity in the workplace, women and ethnic minorities experience difficulty in breaking through the glass ceiling that prevents them from being promoted to higher rungs on the corporate ladder. This invisible barrier to career advancement prevents women and ethnic minorities from holding managerial or executive jobs regardless of their accomplishments and merits (Schueller-Weidekamm & Kautzky-Willer, 2012).

## Review Connect Reflect

**LG5** Explain the key dimensions of career and work in early adulthood.

### Review

- What are some developmental changes in careers and work?
- What does Damon argue is missing in many individuals' career pursuits?
- Which occupational areas are likely to offer the greatest increase in jobs in the next decade?
- What are some important things to know about work?
- What characterizes diversity in the workplace?

### Connect

- Relate what you have previously learned about gender to how gender affects work opportunities and work environments.

### Reflect Your Own Personal Journey of Life

- If you are an emerging adult, what careers do you want to pursue? How much education will they require? If you are older, how satisfied are you with your career choices? Explain.

## topical connections *looking forward*

At some point in middle age, more time stretches behind us than ahead of us. Midlife is changing—entered later and lasting longer—for many people. Middle adulthood is a time of declining physical skills and expanding responsibility, as well as balancing work and relationships. For many individuals, cognitive abilities peak in middle age, although some aspects of information processing, such as perceptual speed and memory, decline. Work continues to be central to people's lives in middle adulthood. Middle age also is when individuals become more interested in understanding the meaning of life.

## reach your learning goals

# Physical and Cognitive Development in Early Adulthood

### 1 The Transition from Adolescence to Adulthood

Becoming an Adult

**LG1** Describe the transition from adolescence to adulthood.

- Emerging adulthood is the term given to the transition from adolescence to adulthood. This period ranges from about 18 to 25 years of age, and it is characterized by experimentation and exploration. Today's emerging and young adults are experiencing emerging and early

### The Transition from High School to College

adulthood quite differently from their counterparts in earlier generations. There is both continuity and change in the transition from adolescence to adulthood. Two criteria for adult status are economic independence and taking responsibility for the consequences of one's actions.

- The transition from high school to college can have both positive and negative aspects. Although students may feel more grown up and be intellectually challenged by academic work, for many the transition involves a focus on the stressful move from being the oldest and most powerful group of students to being the youngest and least powerful. U.S. college students today report experiencing more stress and depression than college students in the past.

## 2 Physical Development

### Physical Performance and Development

### Health

### Eating and Weight

### Regular Exercise

### Substance Abuse

LG2

Identify the changes in physical development in young adults.

- Peak physical performance is often reached between 19 and 26 years of age. Toward the latter part of early adulthood, a detectable slowdown in physical performance is apparent for most individuals.
- Emerging adults have more than twice the mortality rate of adolescents, with males being mainly responsible for the increase. Despite their higher mortality rate, emerging adults in general have few chronic health problems. Many emerging adults develop bad health habits that can impair their health later in life.
- Obesity is a serious problem, with about 33 percent of Americans overweight enough to be at increased health risk. Hereditary and environmental factors are involved in obesity. Most diets don't work over the long term. For those that do, exercise is usually an important component. People with binge eating disorder (BED) frequently binge but do not purge and thus are often overweight.
- Both moderate and intense exercise programs lead to important physical and psychological gains.
- By the mid-twenties, a reduction in alcohol and drug use often takes place. Binge drinking among college students is still a major concern and can cause students to miss classes, have trouble with police, and engage in unprotected sex. Alcoholism is a disorder that impairs an individual's health and social relationships. Fewer young adults are smoking cigarettes now than in past decades, although the use of e-cigarettes is becoming more common. Most adult smokers would like to quit, but their addiction to nicotine makes quitting a challenge.

## 3 Sexuality

### Sexual Activity in Emerging Adulthood

### Sexual Orientation and Behavior

### Sexually Transmitted Infections

### Forcible Sexual Behavior and Sexual Harassment

LG3

Discuss sexuality in young adults.

- Emerging adulthood is a time during which most individuals are sexually active and become married. Emerging adults have sexual intercourse with more individuals than young adults, but they have sex less frequently. Also, casual sex is more common in emerging adulthood than young adulthood.
- In the 1994 Sex in America survey, American adults' sexual lives were portrayed as more conservative than was previously believed. An individual's sexual preference likely is the result of a combination of genetic, hormonal, cognitive, and environmental factors.
- Also called STIs, sexually transmitted infections are contracted primarily through sexual contact. The STI that has received the most attention in the last several decades is infection with HIV, which can lead to AIDS (acquired immune deficiency syndrome). A person with AIDS has such a weakened immune system that even a cold can be life-threatening.
- Rape is forcible sexual intercourse with a person who does not give consent. Date or acquaintance rape involves coercive sexual activity directed at someone with whom the perpetrator is at least casually acquainted. Sexual harassment occurs when one person uses his or her power over another individual in a sexual manner, which can result in serious psychological consequences for the victim.

## 4 Cognitive Development

Cognitive Stages

Creativity

**LG4** Characterize cognitive changes in early adulthood.

- Formal operational thought is Piaget's final cognitive stage, beginning at about age 11 to 15. According to Piaget, although adults are quantitatively more knowledgeable than adolescents, adults do not enter a new, qualitatively different stage. However, some have proposed that young adults move into a qualitatively higher stage called postformal thought that is more reflective, relativistic, and contextual; provisional; realistic; and recognized as being influenced by emotion.
- Creativity peaks in adulthood, often during the forties, and then declines. However, there is extensive individual variation in lifetime creative output. Csikszentmihalyi proposed that the first step toward living a more creative life is to cultivate curiosity and interest.

## 5 Careers and Work

Developmental Changes

Finding a Path to Purpose

Monitoring the Occupational Outlook

The Impact of Work

Diversity in the Workplace

**LG5** Explain the key dimensions of career and work in early adulthood.

- Many young children have idealistic fantasies about a career. In the late teens and early twenties, their career thinking has usually turned more serious. By their early to mid-twenties, many individuals have completed their education or training and started in a career. In the remainder of early adulthood, they seek to establish their emerging career and start moving up the career ladder. Many individuals believe in the career mystique, but recently this has become a myth for increasing numbers of Americans.
- Damon argues that too many individuals have not found a path to purpose in their career development. He concludes that too often individuals focus on short-term goals and don't explore the big, long-term picture of what they want to do with their lives.
- Jobs that require a college education are expected to be the fastest-growing and highest-paying occupational sector in the United States over the next decade. Education, health care, business, and professional services are projected to account for most of the new jobs.
- Work defines people in fundamental ways and is a key aspect of their identity. Most individuals spend about one-third of their adult life at work. Seventy-four percent of part-time U.S. college students work while going to college. Working during college can have positive or negative outcomes. Unemployment produces stress regardless of whether the job loss is temporary, cyclical, or permanent. The increasing number of women who work in careers outside the home has led to new work-related issues. Because of the growing number of dual-earner households, there has been a considerable increase in the time men spend in household work and child care.
- The U.S. workplace has become increasingly diverse. Women have become a larger proportion of the workforce in recent years. Latinos are projected to represent a larger percentage of the U.S. workforce than African Americans by 2020.

# SOCIOEMOTIONAL DEVELOPMENT IN EARLY ADULTHOOD

## chapter outline

### ① Stability and Change from Childhood to Adulthood

**Learning Goal 1** Describe stability and change in temperament, and summarize adult attachment styles.

Temperament  
Attachment

Married Adults  
Divorced Adults  
Remarried Adults  
Gay and Lesbian Adults

### ② Attraction, Love, and Close Relationships

**Learning Goal 2** Identify some key aspects of attraction, love, and close relationships.

Attraction  
The Faces of Love  
Falling Out of Love

### ④ Marriage and the Family

**Learning Goal 4** Discuss making marriage work, parenting, and divorce.

Making Marriage Work  
Becoming a Parent  
Dealing with Divorce

### ⑤ Gender and Communication Styles, Relationships, and Classification

**Learning Goal 5** Summarize the influence of gender on communication styles and relationships, and discuss gender classification.

Gender and Communication Styles  
Gender and Relationships  
Gender Classification

## Commitment is an important issue in a romantic relationship for most individuals.

Consider Gwenna, who decides that it is time to have a talk with Greg about his commitment to their relationship (Lerner, 1989, pp. 44–45):

She shared her perspective on both the strengths and weaknesses of their relationship and what her hopes were for the future. She asked Greg to do the same. Unlike earlier conversations, this one was conducted without her pursuing him, pressuring him, or diagnosing his problems with women. At the same time, she asked Greg some clear questions, which exposed his vagueness.

"How will you know when you are ready to make a commitment? What specifically would you need to change or be different than it is today?"

"I don't know," was Greg's response. When questioned further, the best he could come up with was that he'd just feel it.

"How much more time do you need to make a decision one way or another?"

"I'm not sure," Greg replied. "Maybe a couple of years, but I really can't answer a question like that. I can't predict my feelings."

And so it went.

Gwenna really loved this man, but two years (and maybe longer) was longer than she could comfortably wait. So, after much thought she told Greg that she would wait till fall (about ten months), and that she would move on if he couldn't commit himself to marriage by then. She was open about her wish to marry and have a family with him, but she was equally clear that her first priority was a mutually committed relationship. If Greg was not at that point by fall, then she would end the relationship—painful though it would be.

During the waiting period, Gwenna was able to not pursue him and not get distant or otherwise reactive to his expressions of ambivalence and doubt. In this way she gave Greg emotional space to struggle with his dilemma, and the relationship had its best chance of succeeding. Her bottom-line position ("a decision by fall") was not a threat or an attempt to rope Greg in, but rather a clear statement of what was acceptable to her.

When fall arrived, Greg told Gwenna he needed another six months to make up his mind. Gwenna deliberated a while and decided she could live with that. But when the six months were up, Greg was uncertain and asked for more time. It was then that Gwenna took the painful but ultimately empowering step of ending their relationship.

### topical connections *looking back*

A key aspect of socioemotional development in adolescence is an increased interest in identity; many of the key changes in identity, though, take place in emerging adulthood. Seeking autonomy in healthy ways while still being securely attached to parents are important aspects of parent-adolescent relationships. Adolescents also are motivated to spend more time with peers, friendships become more intimate, and romantic relationships begin to play a more important role in adolescents' lives.

# preview

Love is of central importance in each of our lives, as it is in Gwenna and Greg's lives. Shortly, we will discuss the many faces of love, as well as marriage and the family, the diversity of adult lifestyles, and the role of gender in relationships. To begin, though, we will return to the issue of stability and change.

## 1 Stability and Change from Childhood to Adulthood

LG1

Describe stability and change in temperament, and summarize adult attachment styles.

Temperament

Attachment

For adults, socioemotional development revolves around adaptively integrating our emotional experiences into enjoyable relationships with others on a daily basis. Young adults like Gwenna and Greg face choices and challenges in adopting lifestyles that will be emotionally satisfying, predictable, and manageable for them. They do not come to these tasks as blank slates, but do their decisions and actions simply reflect the persons they had become by the end of adolescence?

Current research shows that the first 20 years of life are not meaningless in predicting an adult's socioemotional landscape (Almy & Cicchetti, 2018; Cicchetti, 2017; Goodnight & others, 2017). And there is also every reason to believe that experiences in the early adult years are important in determining what the individual will be like later in adulthood. A common finding is that the smaller the time intervals over which we measure socioemotional characteristics, the more similar an individual will look from one measurement to the next. Thus, if we measure an individual's self-esteem at the age of 20 and then again at the age of 30, we will probably find more stability than if we measured the individual's self-esteem at the age of 10 and then again at the age of 30.

In trying to understand the young adult's socioemotional development, it would be misleading to look at an adult's life only in the present tense, ignoring the unfolding of social relationships and emotions (Dowling & others, 2017). So, too, it would be a mistake to search only through a 30-year-old's first 5 to 10 years of life in trying to understand why he or she is having difficulty in a close relationship.

### TEMPERAMENT

How stable is temperament? Recall that *temperament* is an individual's behavioral style and characteristic emotional responses. In early adulthood, most individuals show fewer emotional mood swings than they did in adolescence, and they become more responsible and engage in less risk-taking behavior (Charles & Luong, 2011). Along with these signs of a general change in temperament, researchers also find links between some dimensions of childhood temperament and adult personality (Shiner & DeYoung, 2013). For example, in one longitudinal study, children who were highly active at age 4 were likely to be very outgoing at age 23 (Franz, 1996).

Are other aspects of temperament in childhood linked with adjustment in adulthood? Researchers have proposed various ways of describing and classifying types and dimensions of personality. Research has linked several of these types and dimensions during childhood with characteristics of adult personality (Shiner & DeYoung, 2013; Zentner & Shiner, 2012). For example:

- *Easy and difficult temperaments.* In one longitudinal study, children who had an easy temperament at 3 to 5 years of age were likely to be well adjusted as young adults (Chess & Thomas, 1987). In contrast, many children who had a difficult temperament at 3 to 5 years of age were not well adjusted as young adults.
- *Inhibition.* Individuals who had an inhibited temperament in childhood are less likely than other adults to be assertive or experience social support, and more likely to delay entering a stable job track (Lengua & Wachs, 2012; Wachs, 2000). Also, a recent study found that

To what extent is temperament in childhood linked to temperament in adulthood?  
(Top) ©Volodymyr Tverdoklib/Shutterstock;  
(bottom) ©elenaleonova/Getty Images

### developmental connection

#### Temperament

Among the main temperament categories are Chess and Thomas' easy and difficult; Kagan's inhibition; and Rothbart and Bates' effortful control (self-regulation). Connect to "Socio-emotional Development in Infancy."

Initial Temperament Trait: Inhibition			
	Child A	Intervening Context	
Caregivers	Caregivers (parents) who are sensitive and accepting, and let child set his or her own pace.	Caregivers who use inappropriate “low-level control” and attempt to force the child into new situations.	
Physical Environment	Presence of “stimulus shelters” or “defensible spaces” that the children can retreat to when there is too much stimulation.	Child continually encounters noisy, chaotic environments that allow no escape from stimulation.	
Peers	Peer groups with other inhibited children with common interests, so the child feels accepted.	Peer groups consist of athletic extroverts, so the child feels rejected.	
Schools	School is “undermanned,” so inhibited children are more likely to be tolerated and feel they can make a contribution.	School is “overmanned,” so inhibited children are less likely to be tolerated and more likely to feel undervalued.	
Personality Outcomes			
As an adult, individual is closer to extraversion (outgoing, sociable) and is emotionally stable.		As an adult, individual is closer to introversion and has more emotional problems.	

**FIGURE 1**

**TEMPERAMENT IN CHILDHOOD, PERSONALITY IN ADULTHOOD, AND INTERVENING CONTEXTS.** Varying experiences with caregivers, the physical environment, peers, and schools can modify links between temperament in childhood and personality in adulthood. The example given here is for inhibition.

disinhibition in the toddler years was linked to career stability in middle adulthood (Blatny & others, 2015). Also in this study, disinhibition in childhood predicted self-efficacy in adulthood. And in a longitudinal study from 8 to 35 year of age, relative to a low-stable trajectory of shyness, an increasing trajectory of shyness was linked to social anxiety, mood disorders, and substance use in adulthood (Tang & others, 2017).

- *Ability to control one’s emotions.* In one longitudinal study, when 3-year-old children showed good control of their emotions and were resilient in the face of stress, they were likely to continue to handle emotions effectively as adults (Block, 1993). By contrast, when 3-year-olds had low emotional control and were not very resilient, they were likely to show problems in these areas as young adults. Also, a recent study revealed a high level of emotionality at 6 years of age was associated with depression in emerging adulthood (Bould & others, 2015). Another longitudinal study found that emotion dysregulation in the fifth grade was linked to engaging in violent crime at 22 to 23 years of age (Kalvin & Bierman, 2017).

In sum, these studies reveal some continuity between certain aspects of temperament in childhood and adjustment in early adulthood (Rothbart, 2011). However, as Theodore Wachs (1994, 2000) has proposed, links between temperament in childhood and personality in adulthood might vary depending on the intervening contexts in individuals’ experience. For example, Figure 1 describes contexts in which an infant who displayed an inhibited temperament might or might not develop a relatively sociable adult personality.

### developmental connection

#### Attachment

Secure and insecure attachment have been proposed as important aspects of infants’ and adolescents’ socioemotional development. Connect to “Socioemotional Development in Infancy” and “Socioemotional Development in Adolescence.”

### ATTACHMENT

Like temperament, attachment appears during infancy and plays an important part in socioemotional development (Hoffman & others, 2017; Leerkes & others, 2017; Thompson, 2016). We have discussed its role in infancy and adolescence. How do these earlier patterns of attachment and adults’ attachment styles influence the lives of adults?

Although relationships with romantic partners differ from those with parents, romantic partners fulfill some of the same needs for adults as parents do for their children. Recall that *securely attached* infants are defined as those who use the caregiver as a secure base from which to explore the environment. Similarly, adults may count on their romantic partners to be a secure base to which they can return and obtain comfort and security in stressful times (Arriaga & others, 2018; Gewirtz-Meydan & Finzi-Dottan, 2018; Simpson & Steven Rholes, 2017).

How are attachment patterns in childhood linked to relationships in emerging and early adulthood?  
(Left) ©Runstudio/Taxi Japan/Getty Images; (right) ©Jade/Getty Images

Do adult attachment patterns with partners reflect childhood and adolescent attachment patterns with parents? In a widely cited retrospective study, Cindy Hazan and Phillip Shaver (1987) revealed that young adults who were securely attached in their romantic relationships were more likely to describe their early relationship with their parents as securely attached. Also, in a longitudinal study, infants who were securely attached at 1 year of age were securely attached 20 years later in their adult romantic relationships (Steele & others, 1998). Further, a longitudinal study revealed that securely attached infants were in more stable romantic relationships in adulthood than their insecurely attached counterparts (Salvatore & others, 2011). A longitudinal study found that insecure avoidant attachment at 8 years of age was linked to a lower level of social initiative and prosocial behavior and a higher level of social anxiety and loneliness at 21 years of age (Fransson & others, 2016). And in a longitudinal study from 13 to 72 years of age, avoidant attachment declined across the life span and being in a relationship predicted lower levels of anxious and avoidant attachment across adulthood (Chopik, Edelstein, & Grimm, 2018). However, in another study links between early attachment styles and later attachment styles were lessened by stressful and disruptive experiences such as the death of a parent or instability of caregiving (Lewis, Feiring, & Rosenthal, 2000).

Consistently positive caregiving over a number of years is likely an important factor in connecting early attachment with functioning later in development. A longitudinal study revealed that changes in attachment security/insecurity from infancy to adulthood were linked to stresses and supports in socioemotional contexts (Van Ryzin, Carlson, & Sroufe, 2011). The study just described (Van Ryzin, Carlson, & Sroufe, 2011) reflects an increasingly accepted view of the nature of attachment and its influence on development. That is, it is important to recognize that attachment security in infancy does not always by itself produce long-term positive outcomes, but rather is linked to later outcomes through connections with the way children, adolescents, and adults subsequently experience various social contexts as they develop (Fraley & Shaver, 2016; Roisman & others, 2016). Recall that the Van Ryzin, Carlson, and Sroufe (2011) study reflects a *developmental cascade model*, which involves connections across domains over time that influence developmental pathways and outcomes (Almy & Cicchetti, 2018; Cicchetti, 2017; Pasco-Fearon & others, 2016).

Following is a description of the widely used measure of adult attachment created by Hazan and Shaver (1987, p. 515):

*Read each paragraph and then place a check mark next to the description that best describes you:*

1. I find it relatively easy to get close to others and I am comfortable depending on them and having them depend on me. I don't worry about being abandoned or about someone getting too close to me.

2. I am somewhat uncomfortable being close to others. I find it difficult to trust them completely and to allow myself to depend on them. I get nervous when anyone gets too close to me and it bothers me when someone tries to be more intimate with me than I feel comfortable with.
3. I find that others are reluctant to get as close as I would like. I often worry that my partner doesn't really love me or won't want to stay with me. I want to get very close to my partner, and this sometimes scares people away.

These items correspond to three attachment styles—secure attachment (option 1 above) and two insecure attachment styles (avoidant—option 2 above, and anxious—option 3 above):

- **Secure attachment style.** Securely attached adults have positive views of relationships, find it easy to get close to others, and are not overly concerned with or stressed out about their romantic relationships. These adults tend to enjoy sexuality in the context of a committed relationship and are less likely than others to have one-night stands.
- **Avoidant attachment style.** Avoidant individuals are hesitant about getting involved in romantic relationships and once they are in a relationship tend to distance themselves from their partner.
- **Anxious attachment style.** These individuals demand closeness, are less trusting, and are more emotional, jealous, and possessive.

The majority of adults (about 60 to 80 percent) describe themselves as securely attached, and not surprisingly adults prefer having a securely attached partner (Zeifman & Hazan, 2008).

Researchers are studying links between adults' current attachment styles and many aspects of their lives (Arriaga & others, 2018; Hocking & others, 2018; Mikulincer & Shaver, 2016; Simpson & Rholes, 2017; Umemura & others, 2018). For example, securely attached adults are more satisfied with their close relationships than insecurely attached adults, and the relationships of securely attached adults are more likely to be characterized by trust, commitment, and longevity.

The following studies have confirmed the importance of adult attachment styles in people's lives:

- Attachment-anxious individuals showed strong ambivalence toward a romantic partner (Mikulincer & others, 2010).
- Insecurely attached adults had a higher level of social anxiety than their securely attached counterparts (Notzon & others, 2016).
- Attachment-anxious individuals had higher levels of health anxiety (Maunder & others, 2017).
- Insecurely attached adults had higher levels of social anxiety than securely attached adults (Manning & others, 2017).
- Young adults with an anxious attachment were more likely to be characterized by higher negative affect, stress, and perceived social rejection; those with an avoidant attachment were more likely to be characterized by less desire to be with others when alone (Sheinbaum & others, 2015).
- Insecure attachment in adults was associated with the development of disease and chronic illness, especially cardiovascular system problems such as high blood pressure, heart attack, and stroke (McWilliams & Bailey, 2010).
- Adults with avoidant and anxious attachment patterns had a lower level of sexual satisfaction than their securely attached counterparts (Brassard & others, 2012).
- In two longitudinal studies of newlywed marriages, spouses were more likely to engage in infidelity when either they or their partner had a highly anxious attachment style (Russell, Baker, & McNulty, 2013).

Leading experts Mario Mikulincer and Phillip Shaver (2007, 2015, 2016) reached the following conclusions about the benefits of secure attachment. Individuals who are securely attached have a well-integrated sense of self-acceptance, self-esteem, and self-efficacy. They are able to control their emotions, are optimistic, and are resilient. When they face stress and adversity, they activate cognitive representations of being securely attached, are mindful of what is happening around them, and choose effective coping strategies.

If you have an insecure attachment style, are you stuck with it and does it doom you to have problematic relationships? Attachment categories are somewhat stable in adulthood,

*What are some key dimensions of attachment in adulthood, and how are they related to relationship patterns and well-being?*

©MM Productions/Corbis

**secure attachment style** An attachment style that describes adults who have positive views of relationships, find it easy to get close to others, and are not overly concerned or stressed out about their romantic relationships.

**avoidant attachment style** An attachment style that describes adults who are hesitant about getting involved in romantic relationships and once in a relationship tend to distance themselves from their partner.

**anxious attachment style** An attachment style that describes adults who demand closeness, are less trusting, and are more emotional, jealous, and possessive.

but adults do have the capacity to change their attachment thinking and behavior (Mikulincer & Shaver, 2016). Although attachment insecurities are linked to relationship problems, attachment style makes only a moderate contribution to relationship functioning because other factors contribute to relationship satisfaction and success. Later in the chapter, we will discuss such factors in our coverage of marital relationships.

### Review Connect Reflect

**LG1** Describe stability and change in temperament, and summarize adult attachment styles.

#### Review

- How stable is temperament from childhood to adulthood?
- What attachment styles characterize adults, and how are they linked to relationship outcomes?

#### Connect

- What is your attachment style? How do you think it affects your relationships?

## 2 Attraction, Love, and Close Relationships

Attraction

The Faces of Love

**LG2**

Identify some key aspects of attraction, love, and close relationships.

Falling Out of Love

These are the themes of our exploration of close relationships: how these relationships get started, the faces of love, and falling out of love.

### Attraction

What attracts people like Gwenna and Greg to each other and motivates them to spend more time together? How important are first impressions, personality traits, and physical attraction in determining the relationships we form?

**First Impressions** When we first meet someone, typically the new acquaintance quickly makes an impression (King, 2017, 2019). That first impression can have lasting effects (South Palomares, Sutherland, & Young, 2018). How fast do we make these initial impressions of others? In one study, judgments made after just a 100-millisecond exposure time to unfamiliar faces were sufficient for individuals to form an impression (Willis & Todorov, 2006).

Are first impressions accurate? Numerous studies have found that immediate impressions can be accurate. Based on very little evidence, such as that provided by photographs, very brief interactions, or video clips, individuals can accurately detect a person's romantic interest in them (Place & others, 2012), their tendency to be violent (Stillman, Maner, & Baumeister, 2010), and their sexual orientation (Stern & others, 2013). However, in some cases first impressions can be misleading. In a recent study, individuals who encountered others with attractive faces were more likely to overestimate their intelligence (Talamas, Mavor, & Perrett, 2016).

**Familiarity and Similarity** Although first impressions may contribute to whether a relationship will develop, much more is involved in whether a relationship will endure. Familiarity may breed contempt, as the old saying goes, but researchers have found that familiarity is an important condition for a close relationship to develop. For the most part, friends and lovers are people who have been around each other for a long time; they may have grown up together, gone to high school or college together, worked together, or gone to the same social events (Anderson & Sabatelli, 2011).

Another old saying, "Birds of a feather flock together," also helps to explain attraction. Overall, our friends and lovers are much more like us than unlike us (Guerrero, Andersen, & Afifi, 2011). Friends and lovers tend to have similar attitudes, values, lifestyles, and physical

(Left) Manti Te'o; (right) Michelle Przybyksi and Andy Lalinde.

(Left) ©John Biever/Sports Illustrated/Getty Images; (right) Courtesy of Michelle and Andres Lalinde

attractiveness. For some characteristics, though, opposites may attract. An introvert may wish to be with an extravert, or someone with little money may wish to associate with someone who is wealthy, for example.

Why are people attracted to others who have similar attitudes, values, and lifestyles? **Consensual validation** is one reason. Our own attitudes and values are supported when someone else's attitudes and values are similar to ours—their attitudes and values validate ours. Another reason similarity matters is that people tend to shy away from the unknown. We often prefer to be around people whose attitudes and values we can predict. And similarity implies that we will enjoy doing things with another person who likes the same things and has similar attitudes.

Recently, attraction has not only taken place in person but also over the Internet (Fullwood & Attrill-Smith, 2018; Jung & others, 2017; Potarca, 2017; Sanchez, Munoz-Fernandez, & Ortega-Ruiz, 2017). In a recent U.S. survey, 10 percent of 18- to 24-year-olds, 22 percent of 25- to 34-year-olds, and 17 percent of 35- to 44-year-olds reported that they had used online dating sites or apps (Pew Research Center, 2015a). In their twenties, women have more online pursuers than men, but in their forties men have more online pursuers.

When online dating first began in 2005, it was viewed by most people as not being a good way to meet people, but in a recent national survey, a majority of Americans said that online dating is a good way to meet people (Pew Research Center, 2015a).

Is looking for love online likely to work out? It didn't work out so well in 2012 for Notre Dame linebacker Manti Te'o, whose online girlfriend turned out to be a "catfish," someone who fakes an identity online. Connecting online for love did turn out positively for two Columbia University graduate students, Michelle Przybyksi and Andy Lalinde (Steinberg, 2011). They lived only a few blocks away from each other, so soon after they communicated online through DatemySchool.com, an online dating site exclusively for college students, they met in person, really hit it off, applied for a marriage license 10 days later, and eventually got married.

However, an editorial by Samantha Nickalls (2012) in *The Tower*, the student newspaper at Arcadia University in Philadelphia, argued that online dating sites might be okay for people in their thirties and older but not for college students. She commented:

The dating pool of our age is huge. Huge. After all, marriage is not on most people's minds when they're in college, but dating (or perhaps just hooking up) most certainly is. A college campus, in fact, is like living a dating service because the majority of people are looking for the same thing you are. As long as you put yourself out there, flirt a bit, and be friendly, chances are that people will notice.

©Fran Orford, www.francartoons.com

**consensual validation** An explanation of why individuals are attracted to people who are similar to them. Our own attitudes and behavior are supported and validated when someone else's attitudes and behavior are similar to our own.

Some critics argue that online romantic relationships lose the interpersonal connection while others emphasize that the Internet may benefit shy or anxious individuals who find it difficult to meet potential partners in person (Holmes, Little, & Welsh, 2009). One problem with online matchmaking is that many individuals misrepresent their characteristics, such as how old they are, how attractive they are, and their occupation. Recent data indicate that men lie most about their age, height, and income; women lie most about their weight, physical build, and age (statisticbrain.com, 2017). Despite such dishonesty, some researchers have found that romantic relationships initiated on the Internet are more likely than relationships established in person to last for more than two years (Bargh & McKenna, 2004). And a national study of more than 19,000 individuals found that more than one-third of marriages now begin online (Cacioppo & others, 2013). Also in this study, marriages that began online were slightly less likely to break up and were characterized by slightly higher marital satisfaction than those that started in traditional offline contexts.

What do you think? Is searching online for romantic relationships a good idea? What are some cautions that should be taken if you pursue an online romantic relationship?

**Physical Attractiveness** As important as familiarity and similarity may be, they do not explain the spark that often ignites a romantic relationship: physical attractiveness. How important is physical attractiveness in relationships? Psychologists do not consider the link between physical beauty and attraction to be as clear-cut as many advertising agencies would like us to believe. For example, psychologists have determined that men and women differ on the importance of good looks when they seek an intimate partner. Women tend to rate as most important such traits as considerateness, honesty, dependability, kindness, understanding, and earning prospects; men prefer good looks, cooking skills, and frugality (Buss & Barnes, 1986; Eastwick & Finkel, 2008). And in one study, researchers found that partner physical attractiveness played a larger role in predicting husbands' marital satisfaction than in predicting wives' marital satisfaction (Meltzer & others, 2014).

Complicating research about the role of physical attraction are changing standards of what is deemed attractive. The criteria for beauty can differ not just across cultures but over time within cultures as well. In the 1950s, the ideal of female beauty in the United States was typified by the well-rounded figure of Marilyn Monroe. Today, Monroe's 135-pound, 5-foot, 5-inch physique might be regarded as a bit overweight. The current ideal physique for both men and women is neither pleasingly plump nor extremely slender.

The force of similarity also operates at a physical level. We usually seek out someone at our own level of attractiveness in physical characteristics as well as social attributes. Research validates the **matching hypothesis**, which states that although we may prefer a more attractive person in the abstract, in the real world we end up choosing someone who is close to our own level of attractiveness.

Love is a canvas furnished by nature and embroidered by imagination.

## THE FACES OF LOVE

Once we are initially attracted to another person, other opportunities exist that may deepen the relationship to love. Love refers to a vast and complex territory of human behavior, spanning a range of relationships that includes friendship, romantic love, affectionate love, and consummate love (Berscheid, 2010; Blieszner & Ogletree, 2017, 2018). In most of these types of love, one recurring theme is intimacy (Sternberg & Sternberg, 2018).

**Intimacy** Self-disclosure and the sharing of private thoughts are hallmarks of intimacy (Prager, 2013; Williams, Sawyer, & Wahlstrom, 2017). Adolescents have an increased need for intimacy. At the same time, they are engaged in the essential tasks of developing an identity and establishing their independence from their parents. Juggling the competing demands of intimacy, identity, and independence also becomes a central task of adulthood.

Recall that Erik Erikson (1968) argues that identity versus identity confusion—pursuing who we are, what we are all about, and where we are going in life—is the most important issue to be negotiated in adolescence. In early adulthood, according to Erikson, after individuals are well on their way to establishing stable and successful identities, they enter the sixth developmental stage, which is intimacy versus isolation. Erikson describes intimacy as finding oneself while losing oneself in another person, and it requires a commitment to another person. If a person fails to develop an intimate relationship in early adulthood, according to Erikson, isolation results.

### developmental connection

#### Erikson's Theory

Erikson's adolescence stage is identity versus identity confusion and his middle adulthood stage is generativity versus stagnation. Connect to “Socioemotional Development in Adolescence” and “Socioemotional Development in Middle Adulthood.”

**matching hypothesis** Theory that although we prefer a more attractive person in the abstract, in the real world we end up choosing someone who is close to our own level of attractiveness.

*Why is intimacy an important aspect of early adulthood?*

## We are what we love.

—ERIK ERIKSON

Danish-Born American Psychoanalyst and Author,  
20th Century

**romantic love** Also called passionate love or *eros*, romantic love has strong sexual and infatuation components and often predominates early in a love relationship.

**affectionate love** In this type of love, also called companionate love, an individual desires to have the other person near and has a deep, caring affection for the other person.

One study confirmed Erikson's theory that identity development in adolescence is a precursor to intimacy in romantic relationships during emerging adulthood (Beyers & Seiffge-Krenke, 2010). And a meta-analysis revealed a positive link between identity development and intimacy, with the connection being stronger for men than for women (Arseth & others, 2009).

**Friendship** Increasingly researchers are finding that friendship plays an important role in development throughout the life span (Blieszner, 2016). Most U.S. men and women have a best friend—92 percent of women and 88 percent of men have a best friend of the same sex (Blieszner, 2009). Many friendships are long-lasting, as 65 percent of U.S. adults have known their best friend for at least 10 years and only 15 percent have known their best friend for less than 5 years. Adulthood brings opportunities for new friendships as individuals move to new locations and may establish new friendships in their neighborhood or at work (Blieszner & Ogletree, 2017, 2018).

**Romantic Love** Some friendships evolve into **romantic love**, which is also called passionate love or *eros*. Romantic love has strong components of sexuality and infatuation, and it often predominates in the early part of a love relationship (Berscheid, 2010). A meta-analysis found that males show higher avoidance and lower anxiety about romantic love than females do (Del Giudice, 2011).

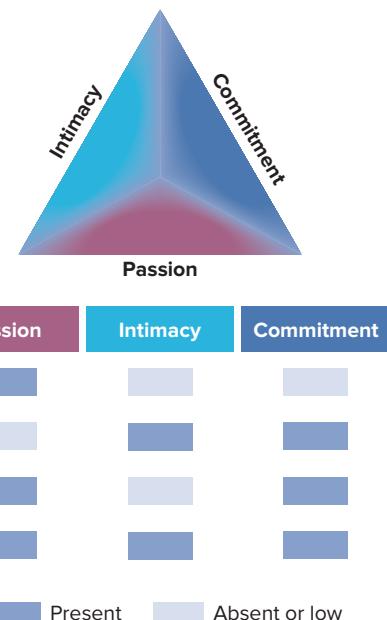

A complex intermingling of different emotions goes into romantic love—including such emotions as passion, fear, anger, sexual desire, joy, and jealousy (Del Giudice, 2011). Well-known love researcher Ellen Berscheid (1988) says that sexual desire is the most important ingredient of romantic love. Obviously, some of these emotions are a source of anguish, which can lead to other issues such as depression. Indeed, one study revealed that a heightened state of romantic love in young adults was linked to stronger depression and anxiety symptoms but better sleep quality (Bajoghli & others, 2014). And a recent study confirmed that declaring a relationship status on Facebook was associated with both romantic love and jealousy (Orosz & others, 2015).

How do romantic relationships change in emerging adulthood? In a recent study that spanned 10 years, short-term relationships were supported more as individuals moved into emerging adulthood (Lantagne, Furman, & Novak, 2017). Long-term adolescent relationships were both supportive and turbulent, characterized by elevated levels of support, negative interactions, higher control, and more jealousy. In emerging adulthood, long-term relationships continued to have high levels of support but negative interactions, control, and jealousy decreased.

**Affectionate Love** Love is more than just passion (Youyou & others, 2017). **Affectionate love**, also called *companionate love*, is the type of love that occurs when someone desires to have the other person near and has a deep, caring affection for the person. The early stages of love have more romantic love ingredients—but as love matures, passion tends to give way to affection (Sternberg & Sternberg, 2018).

**Consummate Love** So far we have discussed two forms of love: romantic (or passionate) and affectionate (or companionate). According to Robert J. Sternberg (1988), these are not the only forms of love. Sternberg proposed a triarchic theory of love in which love can be thought of as a triangle with three main dimensions—passion, intimacy, and commitment. Passion, as described earlier in the romantic love section, is physical and sexual attraction to another. Intimacy relates to the emotional feelings of warmth, closeness, and sharing in a relationship. Commitment is the cognitive appraisal of the relationship and the intent to maintain the relationship even in the face of problems.

In Sternberg's theory, the strongest, fullest form of love is *consummate love*, which involves all three dimensions (see Figure 2). If passion is the only ingredient in a relationship (with intimacy and commitment low or absent), we are merely *infatuated*. An affair or a fling in which there is little intimacy and even less commitment is an example. A relationship marked by intimacy and commitment but low or lacking in passion is called *affectionate love*, a pattern often found among couples who have been married for many years. If passion and commitment are present but intimacy is not, Sternberg calls the relationship *fatuous love*, as when one person worships another from a distance. But if couples share all three dimensions—passion, intimacy, and commitment—they experience consummate love (Sternberg & Sternberg, 2018).

**FIGURE 2**

**STERNBERG'S TRIANGLE OF LOVE.** Sternberg identified three dimensions of love: passion, intimacy, and commitment. Various combinations of these dimensions result in infatuation, affectionate love, fatuous love, and consummate love.

**Cross-Cultural Variations in Romantic Relationships** Culture has strong influences on many aspects of human development, including romantic relationships (Gao, 2016). In collectivist countries like China and Korea, intimacy is more diffused in love because of the strong group emphasis on connections outside of a romantic love relationship. By contrast, in individualistic countries such as the United States and most European countries, intimacy is often more intensified because an individual's social network is more likely to be smaller and less group-oriented (Gao, 2016). Also, research indicates that greater passion characterizes U.S. romantic relationships than Chinese romantic relationships (Gao, 2001). And researchers have found that self-disclosure is more common in U.S. romantic relationships than Japanese romantic relationships (Kito, 2005). Feelings of commitment are stronger in Chinese romantic relationships than in U.S. romantic relationships (Dion & Dion, 1993).

In a recent exploration of cross-cultural variations, romantic relationships were studied in three countries—Japan, France, and Argentina (Ansari, 2015). In Japan, the marriage rate is declining so rapidly that the Japanese government is very concerned that this could lead to a considerable drop in Japan's population. In 2013, 45 percent of Japanese women 16 to 24 years of age reported that they were not interested in or despised having sexual contact. Also, the percentage of Japanese men and women who aren't involved in any romantic relationship has increased significantly in recent years.

In Brazil, romantic interest is much stronger than in Japan (Ansari, 2015). Sexual and romantic flirtation is a way of life for many Argentinians. Online dating is not nearly as frequent as in the United States, apparently because men are so forward in their romantic pursuits in person.

In France, as in Brazil, interest in passionate love is strong. However, in the three-country comparison, one aspect of French interest in romantic relationships stood out—their affinity for having extramarital affairs. In one comparison, only 47 percent in France reported that having an extramarital affair is morally wrong, compared to 69 percent in Japan and 72 percent in Argentina (Wike, 2014). In this survey, 84 percent of people in the United States said it was morally wrong. In sum, there are striking cultural variations in many aspects of romantic relationships.

Also in this exploration of romantic relationships in different countries, the Middle Eastern country of Qatar also was studied (Ansari, 2015). In Qatar, casual dating is forbidden and public displays of affection can be punished with prison time. However, with the recent advent of smartphones, social media, and the Internet, young adults in Qatar are now contacting each other about co-ed parties in hotel rooms, a private way to hang out away from the monitoring of parents, neighbors, and government officials.

**Relationship Education for Adolescents and Emerging Adults** Traditionally, programs in relationship education have focused on helping committed adult couples to strengthen their relationships. Recently, though, an increasing number of relationship education programs have been developed for adolescents and emerging adults (Hawkins, 2018). *Relationship education* consists of interventions to provide individuals and couples with information and skills that produce positive romantic relationships and marriages. These interventions are diverse and include instruction in basic relationship knowledge and skills to youth in a classroom setting, helping unmarried couples learn more about relationships in small-group settings, and providing premarital education to engaged couples.

A recent meta-analysis of 30 studies of relationship education for adolescents and emerging adults found a positive effect of the programs (Simpson, Leonhardt, & Hawkins, 2018). The skills most often assessed in these studies are interpersonal communication, problem-solving and conflict strategies, and self-regulation (Simpson, Lenhardt, & Hawkins, 2018). The positive effects of relationship education were stronger for emerging adults than for adolescents. They also were stronger for disadvantaged participants than for more advantaged participants.

## FALLING OUT OF LOVE

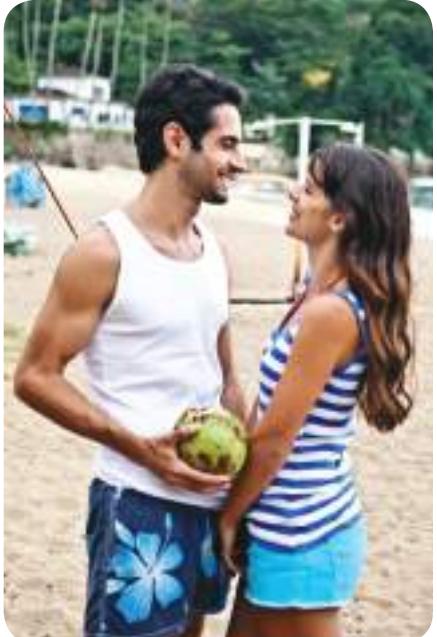

The collapse of a close relationship may feel tragic. In the long run, however, as was the case for Gwenna, our happiness and personal development may benefit from ending a close relationship.

In particular, ending a relationship may be wise if you are obsessed with someone who repeatedly betrays your trust; if you are involved with someone who is draining you emotionally or financially or both; or if you are desperately in love with someone who does not return your feelings.

Being in love when love is not returned can lead to depression, obsessive thoughts, sexual dysfunction, health problems, inability to work effectively, difficulty in making new friends,

## What Are the Positive Outcomes to the Breakup of a Romantic Relationship?

Studies of romantic breakups have mainly focused on their negative aspects (Kato, 2005; Moreau & others, 2011; Simon & Barrett, 2010). Few studies have explored the possibility that a romantic breakup might lead to positive changes.

One study assessed the personal growth that can follow the breakup of a romantic relationship (Tashiro & Frazier, 2003). The participants were 92 undergraduate students who had experienced a relationship breakup in the past nine months. They were asked to describe “what positive changes, if any, have happened as a result of your breakup that might serve to improve your future romantic relationships” (p. 118).

Self-reported positive growth was common following a romantic breakup. Changes were categorized as personal, relational, and environmental. The most commonly reported types of growth were personal changes, which included feeling stronger and more self-confident, more independent, and better off emotionally. Relational positive changes included gaining relational wisdom, and environmental positive changes included having better friendships because of the breakup. Figure 3 provides examples of these positive changes. Women were more likely to report positive growth than men were.

Of course, not all romantic relationships produce positive changes in the aftermath. In a recent large-scale study of more than 9,000 adults, experiencing a romantic breakup lowered individuals’ self-esteem but the effect disappeared one year after the breakup (Luciano & Orth, 2017).

Change category	Exemplars of frequently mentioned responses
Personal positives	1. “I am more self-confident.” 2. “Through breaking up I found I could handle more on my own.” 3. “I didn’t always have to be the strong one, it’s okay to cry or be upset without having to take care of him.”
Relational positives	1. “Better communication.” 2. “I learned many relationship skills that I can apply in the future (for example, the importance of saying you’re sorry).” 3. “I know not to jump into a relationship too quickly.”
Environmental positives	1. “I rely on my friends more. I forgot how important friends are when I was with him.” 2. “Concentrate on school more: I can put so much more time and effort toward school.” 3. “I believe friends’ and family’s opinions count—will seek them out in future relationships.”

**FIGURE 3**  
**EXAMPLES OF POSITIVE CHANGES IN THE AFTERMATH OF A ROMANTIC BREAKUP**

and self-condemnation (Sbarra, 2012). Thinking clearly in such relationships is often difficult because our thoughts are so colored by arousing emotions (Guerrero, Andersen, & Afifi, 2011). A study of unmarried relationship dissolution in 18- to 35-year-olds revealed that experiencing a breakup was linked to an increase in psychological stress and a decrease in life satisfaction (Rhoades & others, 2011).

Are there any positive outcomes to the breakup of a romantic relationship? To find out, see *Connecting Through Research*.

Cohabiting Adults

Married Adults

Divorced Adults

Remarried Adults

Gay and Lesbian Adults

A striking social change in recent decades has been the decreased stigma attached to individuals who do not maintain what were long considered conventional families. Adults today choose many lifestyles and form many types of families (Schwartz & Scott, 2018). They live alone, cohabit, marry, divorce, or live with someone of the same sex.

In his book, *The Marriage-Go-Round*, sociologist Andrew Cherlin (2009) concluded that the United States has more marriages and remarriages, more divorces, and more short-term cohabitation (living together) relationships than most countries. Combined, these lifestyles create more turnover and movement in and out of relationships in the United States than in virtually any other country. Let's explore these varying relationship lifestyles.

## SINGLE ADULTS

Recent decades have seen a dramatic rise in the percentage of single (unmarried) adults. In 2016, 45.2 percent of individuals 18 years and older were single (U.S. Census Bureau, 2017). The increasing number of single adults is the result of rising rates of cohabitation and a trend toward postponing marriage. The United States has a lower percentage of single adults than do many other countries such as Great Britain, Germany, and Japan. Also, the fastest growth in the number of people adopting a single adult lifestyle is occurring in rapidly developing countries such as China, India, and Brazil (Klinenberg, 2012, 2013).

Even when single adults enjoy their lifestyles and are highly competent individuals, they often are stereotyped (Schwartz & Scott, 2012). Stereotypes associated with being single range from the “swinging single” to the “desperately lonely, suicidal” single. Of course, most single adults are somewhere between these extremes.

Common challenges faced by single adults may include forming intimate relationships with other adults, confronting loneliness, and finding a niche in a society that is marriage-oriented. Bella DePaulo (2006, 2011) argues that society has a widespread bias against unmarried adults that is seen in everything from missed perks in jobs to deep social and financial prejudices.

Advantages of being single include having time to make decisions about one's life course, time to develop personal resources to meet goals, freedom to make autonomous decisions and pursue one's own schedule and interests, opportunities to explore new places and try out new things, and privacy. Compared with married adults, single adults are more likely to spend time with friends and neighbors, dine in restaurants, and attend art classes and lectures (Klinenberg, 2012, 2013). Once adults reach the age of 30, they may face increasing pressure to settle down and get married. This is when many single adults make a conscious decision to marry or to remain single.

A nationally representative U.S. survey of more than 5,000 single adults 21 years and older who were not in a committed relationship revealed that men had become more interested in love, marriage, and children than their counterparts were in earlier generations (Match.com, 2011). In this study, today's women desire more independence in their relationships than their mothers did. Across every age group, more women than men reported wanting to pursue their own interests, have personal space, have their own bank account, have regular nights out with friends, and take vacations on their own. In a second national survey, many single adults reported that they were looking for love but not marriage (Match.com, 2012). In this survey, almost 40 percent of the single adults were uncertain about whether they wanted to get married, 34 percent said they did want to marry, and 27 percent said they didn't want to get married. In yet another national survey, millennials were far more likely than older generations to seek romance and commitment (Match.com, 2017). In this recent survey, 40 percent of actively dating single adults have dated someone they met online, while only 24 percent met through a friend. Also in this study, millennials were 48 percent more likely than older generations to have sex before the first date. This “fast sex, slow love” may indicate that millennials want to know as much about someone as possible before committing to a serious relationship (Fisher, 2017). Also in the recent survey, among single men 18 to 70+, 95 percent of single

men favor women initiating the first kiss and also asking for the man's phone number, but only 29 percent of single women actually initiate the first kiss and only 13 percent ask for the man's phone number (Match.com, 2017).

## COHABITING ADULTS

*Cohabitation* refers to living together in a sexual relationship without being married. Cohabitation has undergone considerable changes in recent years (Hognas & Thomas, 2016; Perelli-Harris & others, 2017; Sassler, Michelmore, & Qian, 2018; Tach & Eads, 2015; Thorsen, 2017; Willoughby & Belt, 2016). Cohabitation rates in the U.S. continue to rise (Stepler, 2017). In a recent national poll, the number of cohabiting adults had increased 29 percent from 2007 to 2016, reaching a figure of 18 million adults in a cohabiting relationship (U.S. Census Bureau, 2016). In 2016, 14 percent of U.S. adults 25–34 and 10 percent of those 18–24 years old were cohabiting. Cohabitation rates are even higher in some countries—in Sweden, for example, cohabitation before marriage is virtually universal (Stokes & Raley, 2009). And from 2004 to 2014, the percentage of cohabiting couples grew by 30 percent in Great Britain (Office for National Statistics, 2015).

A national study of women in the United States found the following statistics regarding cohabitation based on interviews conducted between 2006 and 2010 (Copen & others, 2012):

- Length of cohabitation is increasing—an average of 22 months in 2010 compared with 13 months in 1995.
- After three years of cohabiting, 40 percent of women got married, 32 percent continued to live with their partner, and 27 percent had moved out of the cohabiting relationship.
- Education is linked to cohabitation rates—70 percent of women who did not have a high school diploma cohabited in their first union, compared with 47 percent of women who had a bachelor's degree or higher. For women who cohabited in their twenties to forties, among those with higher education the cohabitation was more likely to result in marriage (53 percent) than it was for their counterparts who had not graduated from high school (30 percent).

Further, in a recent large-scale study, women who cohabited within the first year of a sexual relationship were less likely to get married than women who waited more than one year before cohabiting (Sassler, Michelmore, & Qian, 2018).

Some couples view their cohabitation not as a precursor to marriage but as an ongoing lifestyle (Klinenberg, 2013). These couples do not want the official aspects of marriage. One study revealed that young adults' main reasons for cohabiting are to spend time together, share expenses, and evaluate compatibility (Huang & others, 2011). In this study, gender differences emerged regarding perceived drawbacks of cohabiting: men were more concerned about their loss of freedom while women were more concerned about delays in getting married.

Couples who cohabit face certain problems (Braithwaite & Holt-Lunstad, 2017; Fincham & May, 2017). Disapproval by parents and other family members can place emotional strain on the cohabiting couple. Some cohabiting couples have difficulty purchasing and owning property jointly. Legal rights involving the dissolution of the relationship are less clear than in a divorce.

Researchers also have found that cohabiting individuals are not as mentally healthy as their counterparts in committed marital relationships (Braithwaite & Holt-Lunstad, 2017). In a recent study of long-term cohabitation (more than three years) in emerging adulthood, emotional distress was higher in long-term cohabitation than during time spent single, with men especially driving the effect (Memitz, 2018). However, heavy drinking was more common during time spent being single than in long-term cohabitation.

If a couple lives together before they marry, does cohabiting help or harm their chances of having a stable and happy marriage? The majority of studies have found lower rates of marital satisfaction and higher rates of divorce in couples who lived together before getting married (Copen & others, 2012). However, research indicates that the link between premarital cohabitation and marital instability in first marriages has weakened in recent cohorts (Copen & others, 2012; Smock & Gupta, 2013).

What might explain the possibility that cohabiting is linked with divorce more than not cohabiting? The most frequently given explanation is that the

What are some potential advantages and disadvantages of cohabitation?

©OJO Images/Getty Images

less traditional lifestyle of cohabitation may attract less conventional individuals who are not great believers in marriage in the first place. An alternative explanation is that the experience of cohabiting changes people's attitudes and habits in ways that increase their likelihood of divorce.

Recent research has provided clarification of cohabitation outcomes (Hognas & Thomas, 2016; Willoughby & Belt, 2016). One meta-analysis found that the link between cohabitation and marital instability did not hold up when only cohabitation with the eventual marital partner was examined, indicating that these cohabitators may attach more long-term positive meaning to living together (Jose, O'Leary, & Moyer, 2010). Another study also revealed that for first marriages, cohabiting with the spouse without first being engaged was linked to more negative interaction and a higher probability of divorce than cohabiting after engagement (Stanley & others, 2006). In contrast, premarital cohabitation prior to a second marriage placed couples at risk for divorce regardless of whether they were engaged. Researchers have also found that the marriages of couples who had cohabited without being engaged were less likely to survive to the 10- to 15-year mark than the marriages of their counterparts who were engaged when they cohabited (Copen & others, 2012). Also, one analysis indicated that cohabiting does not have a negative effect on marriage if the couple did not have any previous live-in lovers and did not have children prior to the marriage (Cherlin, 2009). And another study concluded that the risk of marital dissolution between cohabitators was much smaller when they cohabited in their mid-twenties and later (Kuperberg, 2014).

## MARRIED ADULTS

Until about 1930, stable marriage was widely accepted as the endpoint of adult development. In the last 70 to 80 years, however, personal fulfillment both inside and outside marriage has emerged as a goal that competes with marital stability. The changing norm of male-female equality in marriage and increasingly high expectations for what a marital relationship should be has produced marital relationships that are more fragile and intense than they were for earlier generations (Schwartz & Scott, 2017; Seecombe, 2015). A study of 502 newlyweds found that nearly all couples had optimistic forecasts of how their marriage would change over the next four years (Lavner, Karney, & Bradbury, 2013). Despite their optimistic forecasts, their marital satisfaction declined across this time frame. Wives with the most optimistic forecasts showed the steepest declines in marital satisfaction.

Some characteristics of marital partners predict whether the marriage will last longer (Williams, Sawyer, & Wahlstrom, 2017). Two such characteristics are education and ethnicity. In a study that involved interviews with more than 22,000 women, both women and men with a bachelor's degree were found to be more likely to delay marriage but also more likely to eventually get married and stay married for more than 20 years (Copen & others, 2012). Also in this study, Asian American women were the most likely of all ethnic groups to be in a first marriage that lasted at least 20 years—70 percent were in a first marriage that lasted this long, compared with 54 percent of non-Latino White women, 53 percent of Latino women, and 37 percent of African American women.

**Marital Trends** In 2016, 50 percent of adults in the United States were married, down from 72 percent in 1960 (Parker & Stepler, 2017). Also, in 2016, the U.S. average age for a first marriage had climbed to 29.5 years for men and 27.4 years for women, higher than at any other point in history (Livingston, 2017). In 1960, the average age for a first marriage in the United States was 23 years for men and 20 years for women. Also, a higher percentage of U.S. adults never marry—in 2014, record percentages of adults 25 years of age and older (23 percent of men, 17 percent of women) had never married. In addition, the increased cohabitation rate in the United States has contributed to the lower percentage of adults who are married (Wang & Parker, 2014). Although marriage rates are declining, the United States continues to be a marrying society, with 78.5 percent of U.S. adults 25 years and older having been married at some point in their lives in 2016.

While marriage rates are declining and the average age of marriage is going up, recent research with emerging and young adults indicates that they view marriage as a very important life pursuit. Indeed, young adults in one study predicted that marriage would be more important in their life than parenting, careers, or leisure activities (Willoughby, Hall, & Goff, 2015). In a recent book, *The Marriage Paradox* (Willoughby & James, 2017), the authors concluded that the importance of marriage to emerging and young adults may motivate them to first build

*Irish Playwright, 20th Century*

a better career and financial foundation to increase the likelihood that their marriage will be successful later. In this perspective, emerging and young adults may not be abandoning marriage because they don't like it or are not interested in it, but rather because they want to position themselves in the best possible way for developing a healthy marital relationship.

One study explored what U.S. never-married men and women are looking for in a potential spouse (Wang, 2014). Following are the percentages who reported that various factors would be very important for them:

<u>Factor</u>	<u>Men</u>	<u>Women</u>
Similar ideas about having and raising children	62	70
A steady job	46	78
Same moral and religious beliefs	31	38
At least as much education	26	28
Same racial or ethnic background	7	10

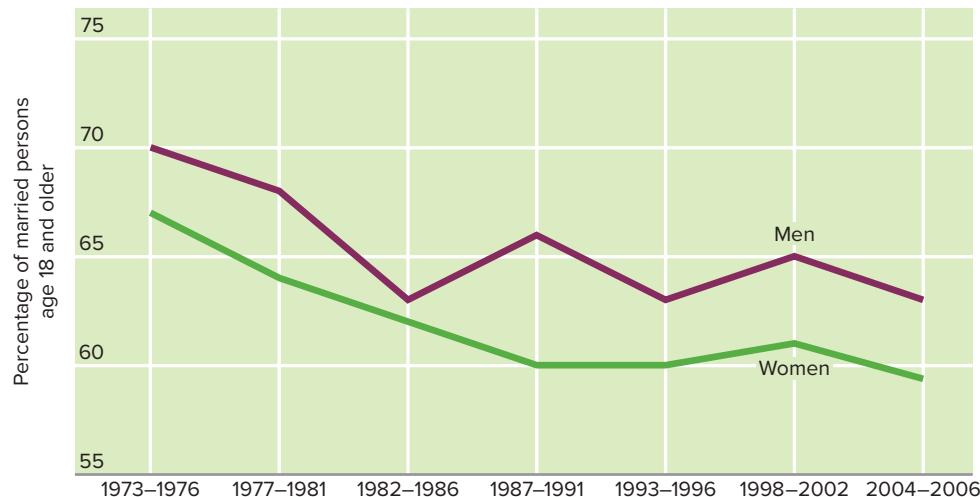

Thus, in this study, never-married men said that the most important factor for a potential spouse was similar ideas about having and raising children, but never-married women placed greater importance on having a steady job.

Is there a best age to get married? Marriages in adolescence are more likely to end in divorce than marriages in adulthood (Copen & others, 2012). However, researchers have not been able to pin down a specific age or age span for getting married in adulthood that is most likely to result in a successful marriage (Furstenberg, 2007).

How happy are people who do marry? The average duration of a marriage in the United States is currently just over nine years. As indicated in Figure 4, the percentage of married individuals in the United States who said their marriages were "very happy" declined from the 1970s through the early 1990s before approaching a plateau (Popenoe, 2009). Notice in Figure 4 that married men consistently report being happier than married women.

**Cross-Cultural Comparisons** Earlier we described cross-cultural variations in romantic relationships and touched on some cultural variations in marriage. Here we further explore other aspects of marriage that vary across cultures (John & others, 2017). For example, as part of China's efforts to control population growth, a 1981 law sets the minimum age for marriage at 22 years for males and 20 for females.

The traits that people look for in a marriage partner vary around the world. In one large-scale study of 9,474 adults from 37 cultures on six continents and five islands, people varied most regarding how much they valued chastity—desiring a marital partner with no previous

**FIGURE 4**  
**PERCENTAGE OF MARRIED PERSONS AGE 18 AND OLDER WITH "VERY HAPPY" MARRIAGES**

experience in sexual intercourse (Buss & others, 1990). Chastity was the most important characteristic in selecting a marital partner in China, India, Indonesia, Iran, Taiwan, and the Palestinian Arab culture. Adults from Ireland and Japan placed moderate importance on chastity. In contrast, adults in Sweden, Finland, Norway, the Netherlands, and Germany generally said that chastity was not important in selecting a marital partner.

Domesticity is also valued in some cultures and not in others. In this study, adults from the Zulu culture in South Africa, Estonia, and Colombia placed a high value on housekeeping skills in their marital preferences. By contrast, adults in the United States, Canada, and all western European countries except Spain said that housekeeping skill was not an important trait in their partner.

Religion plays an important role in marriage in many cultures (King, Abo-Zena, & Weber, 2017; Lazar, 2017). For example, Islam stresses the honor of the male and the purity of the female. It also emphasizes the woman's role in childbearing, child rearing, educating children, and instilling the Islamic faith in their children. In India, a majority of marriages continue to be arranged. However, as more women have entered the workforce in India and moved from rural areas to cities, these Indian women increasingly resist an arranged marriage. In one study conducted in a small village in India, elopement (also called love marriages there) had become more common than arranged marriages (Allendorf, 2013).

International comparisons of marriage also reveal that individuals in Scandinavian countries marry later than Americans, whereas their counterparts in many African, Asian, and Latin American countries marry younger (Waite, 2009). In Denmark, for example, almost 80 percent of the women and 90 percent of the men aged 20 to 24 have never been married. In Hungary, less than 40 percent of the women and 70 percent of the men in this age bracket have never been married. In Scandinavian countries, cohabitation is popular among young adults; however, most Scandinavians eventually marry. In Sweden, women delay marriage until they are about 31, men until they are 33. Some countries, such as Hungary, encourage early marriage and childbearing to offset declines in the population. Like Scandinavian countries, Japan has a high proportion of unmarried young people. However, rather than cohabiting as the Scandinavians do, unmarried Japanese young adults live at home longer with their parents before marrying.

**Premarital Education** Earlier we discussed the positive influence of relationship education for adolescents and emerging adults. Here we further explore premarital education and examine whether it can improve the quality of a marriage and possibly reduce the chances that the marriage will end in divorce. Researchers have found that it can (Markman & others, 2013; Rhoades & others, 2015). For example, a survey of more than 3,000 adults revealed that premarital education was linked to a higher level of marital satisfaction and commitment to a spouse, a lower level of destructive marital conflict, and a 31 percent lower likelihood of divorce (Stanley & others, 2006). The premarital education programs in the study ranged from several hours to 20 hours, with a median of 8 hours. It is recommended that premarital education begin approximately six months to a year before the wedding. Researchers have also found that the effectiveness of a premarital education program was enhanced when the couples had a better level of communication prior to the intervention (Markman & others, 2013).

**The Benefits of a Good Marriage** Are there any benefits to having a good marriage? Yes. Individuals who are married live longer, healthier lives than those who are single, cohabiting, or divorced (Schwartz & Scott, 2017; Williams, Sawyer, & Wahlstrom, 2017). In a recent research review, it was concluded that the experience of divorce or separation confers risk for poor health outcomes, including a 23 percent higher mortality rate (Sbarra, 2015). One study indicated that the longer women were married, the less likely they were to develop a chronic health condition and that the longer men were married, the lower their risk of developing a disease (Dupre & Meadows, 2007). Also, in a recent large-scale study conducted in the United States and six European countries, not being in the labor force was associated with higher mortality but marriage attenuated the increased mortality risk linked to labor force inactivity (Van Hedel & others, 2015). And a recent research review of individuals who were married, divorced, widowed, and single found that married individuals had the best cardiovascular profile and single men the worst (Manfredini & others, 2017). Further, an unhappy marriage can shorten a person's life by an average of four years (Gove, Style, & Hughes, 1990). What are the reasons for the benefits of being married? Overall, people in marriages likely feel less

physically and emotionally stressed, which puts less wear and tear on a person's body. Such wear and tear can lead to physical ailments such as high blood pressure and heart disease, as well as psychological problems such as anxiety, depression, and substance abuse.

## DIVORCED ADULTS

Divorce has become an epidemic in the United States (Braver & Lamb, 2013). However, the divorce rate declined in recent decades, peaking at 5.1 divorces

per 1,000 people in 1981 and declining to 3.2 divorces per 1,000 people in 2014 (Centers for Disease Control and Prevention, 2015). The 2014 divorce rate of 3.2 compares with a marriage rate of 6.9 per 1,000 people in 2014. Although the U.S. divorce rate has dropped, it continues to be one of the highest divorce rates in the world. Russia has the highest divorce rate of the countries surveyed (4.6 divorces per 1,000 people) (OECD, 2016). In the United States, nearly half of first marriages will break up within 20 years (Copen & others, 2012).

Although U.S. divorce rates have increased in all socioeconomic groups, some groups have a higher incidence of divorce (Perelli-Harris & others, 2017). Youthful marriage, low educational level, low income, not having a religious affiliation, having parents who are divorced, and having a baby before marriage are factors that are associated with increases in divorce (Hoelter, 2009). And the following characteristics of one's partner increase the likelihood of divorce: alcoholism, psychological problems, domestic violence, infidelity, and inadequate division of household labor (Perelli-Harris & others, 2017).

Earlier, we indicated that researchers have not been able to pin down a specific age that is the best time to marry so that the marriage will be unlikely to end in a divorce. However, if a divorce is going to occur, it usually takes place early in a marriage; most occur in the fifth to tenth year of marriage, according to U.S. data (National Center for Health Statistics, 2000) (see Figure 5). One study also found that divorce peaked in Finland at approximately five to seven years of marriage, after which the rate of divorce gradually declined (Kulu, 2014). This timing may reflect an effort by partners in troubled marriages to stay in the marriage and try to work things out. If after several years these efforts have not improved the relationship, the couple may then seek a divorce.

What causes people to get divorced? A recent study in Great Britain found no differences in the causes of breakdowns in marriage and cohabitation (Gravning & others, 2017). In this study, the following percentages cited these reasons: "grew apart" (men 39 percent, women 36 percent), "arguments" (27 percent, 30 percent), "unfaithfulness/adultery" (18 percent, 24 percent), "lack of respect, appreciation" (17 percent, 25 percent), and "domestic violence" (4 percent, 16 percent). Both partners experience challenges after a marriage dissolves (Sbarra, Hasselmo, & Bourassa, 2015). Divorced adults have higher rates of depression, anxiety, physical illnesses, suicide, motor vehicle accidents, alcoholism, and mortality (Braver & Lamb, 2013). In a recent study, individuals who were divorced had a higher risk of having alcohol use disorder (Kendler & others, 2017). Also, a recent research review concluded that both divorced men and women are more likely to commit suicide than their married counterparts (Yip & others, 2015). Also, in a recent study, both divorced men and women had a higher risk for having a heart attack than those who were married, but the risk for this cardiovascular disease was higher for divorced women than for divorced men (Dupre & others, 2015). And both divorced women and divorced men complain of loneliness, diminished self-esteem, anxiety about the unknowns in their lives, and difficulty in forming satisfactory new intimate relationships (Hetherington, 2006).

There are gender differences in the process and outcomes of divorce (Braver & Lamb, 2013; Daoulah & others, 2017). A recent study of couples from one to 16 years of a marriage found that wives' increased tension over the course of a marriage was a factor that was consistently linked to an eventual divorce (Birditt & others, 2017). Women are more likely to sense that something is wrong with the marriage and are more likely to seek a divorce than are men. Women also show better emotional adjustment and are more likely to perceive divorce as a

“second chance” to increase their happiness, improve their social lives, and pursue better work opportunities. However, divorce typically has a more negative economic impact on women than it does on men.

Despite all of these stresses and challenges, many people do cope effectively with divorce. Later in this chapter, we consider the varied paths people take after a divorce and suggested strategies for coping.

## REMARRIED ADULTS

Men remarry after a divorce sooner than women do, and men with higher incomes are more likely to remarry than their counterparts with lower incomes. Remarriage occurs sooner for partners who initiate a divorce (especially in the first several years after divorce and for older women) than those who do not (Sweeney, 2009, 2010). Statistics indicate that the remarriage rate in the United States has declined in recent decades, going from 50 of every 1,000 divorced or widowed Americans in 1990 to 29 of every 1,000 in 2011 (U.S. Census Bureau, 2013). One reason for the decline is the dramatic increase in cohabitation in recent years. Men are more likely to remarry than women; in 2013, the remarriage rate was almost twice as high for men as women (40 per 1,000 for men and 21 per 1,000 for women in that year) (Livingston, 2017). Thus, men are either more eager or more able to find new spouses than are women.

Remarried adults often find it difficult to stay remarried. While the divorce rate in first marriages has declined, the divorce rate of remarriages continues to increase (DeLongis & Zwicker, 2017). Why? For one thing, many people remarry not for love but for financial reasons, for help in rearing children, and to reduce loneliness. They also might carry into the stepfamily negative patterns that produced failure in an earlier marriage. Remarried couples also experience more stress in rearing children than parents in never-divorced families (Ganong & Coleman, 2018). One study revealed that positive attitudes about divorce, low marital quality, and divorce proneness were more common among remarried persons than among their counterparts in first marriages (Whitton & others, 2013). Another recent study found that remarried adults had less frequent sex than couples in their first marriage (Stroope, McFarland, & Uecker, 2015).

## GAY AND LESBIAN ADULTS

Until recently, the legal context of marriage created barriers to breaking up that did not exist for same-sex partners. However, the legalization of same-sex marriage in all 50 states in 2015 extended this barrier to same-sex couples (Diamond, 2017; Holley, 2017). In many additional ways, researchers have found that gay and lesbian relationships are similar—in their satisfactions, loves, joys, and conflicts—to heterosexual relationships (Balsam, Rostosky, & Riggle, 2017). For example, like heterosexual couples, gay and lesbian couples need to find a balance of romantic love, affection, autonomy, and equality that is acceptable to both partners (Kurdek, 2006).

Lesbian couples especially place a high priority on equality in their relationships (Fingerhut & Peplau, 2013). One study of couples revealed that over the course of 10 years of cohabitation, partners in gay and lesbian relationships showed a higher average level of relationship quality than heterosexual couples (Kurdek, 2007). A recent survey found that a greater percentage of same-sex, dual-earner couples than different-sex couples said they share laundry (44 versus 31 percent), household repairs (33 versus 15 percent), and routine (74 versus 38 percent) and sick (62 versus 32 percent) child-care responsibilities (Matos, 2015).

It is estimated that of same-sex couples in the United States, lesbian couples are approximately five times more likely to be raising children than are gay couples (Miller & Price, 2013). An increasing number of same-sex couples are adopting children (Farr & Patterson, 2013). The percentage of same-sex couples who have adopted children nearly doubled from 10 percent in 2000 to 19 percent in 2009 (DiBennardo & Gates, 2014; Gates, 2013). Recall that in one study lesbian and gay couples shared child care more than heterosexual couples, with lesbian couples being the most supportive and gay couples the least supportive (Farr & Patterson, 2013).

There are numerous misconceptions about gay and lesbian couples (Farr, 2017; Simon & others, 2018; Fingerhut & Peplau, 2013). Contrary to stereotypes, one partner is masculine and the other feminine in only a small percentage of gay and lesbian couples. Only a small segment of the gay population has a large number of sexual partners, and this is uncommon among lesbians. Furthermore, researchers have found that gays and lesbians prefer long-term,

### developmental connection

#### Parenting

Researchers have found few differences between children who are being raised by gay and lesbian parents and children who are being raised by heterosexual parents. Connect to “Socioemotional Development in Early Childhood.”

committed relationships (Fingerhut & Peplau, 2013). About half of committed gay couples do have an open relationship that allows the possibility of sex (but not affectionate love) outside the relationship. Lesbian couples usually do not have this type of open relationship.

A special concern is the stigma, prejudice, and discrimination that lesbian, gay, and bisexual individuals experience because of widespread social devaluation of same-sex relationships (Balsam, Rostosky, & Riggle, 2017; Conlin, Douglass, & Ouch, 2018; Holley, 2017; Valdiserri & others, 2018). However, one study indicated that many individuals in these relationships saw stigma as bringing them closer together and strengthening their relationship (Frost, 2011).

## Review Connect Reflect

**LG4** Discuss making marriage work, parenting, and divorce.

Making Marriage Work

Becoming a Parent

Dealing with Divorce

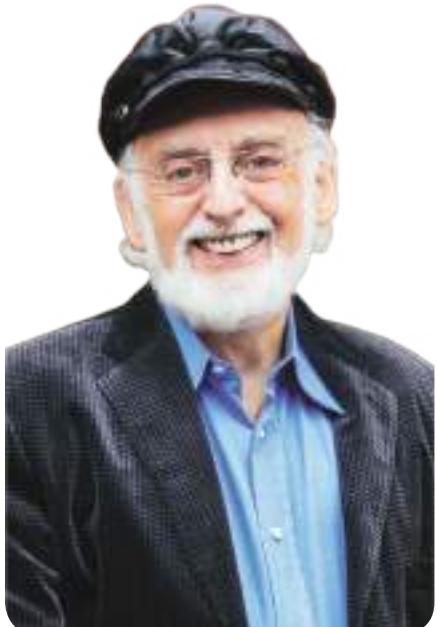

Whatever lifestyles young adults choose, their choices will bring certain challenges. Because many choose the lifestyle of marriage, we'll consider some of the challenges in marriage and suggestions for making it work. We will also examine some challenges in parenting and trends in childbearing. Given the statistics about divorce rates in the previous section, we'll then consider how to deal with divorce.

### MAKING MARRIAGE WORK

John Gottman (1994, 2006, 2011; Gottman & Silver, 1999, 2015) has been studying married couples' lives since the early 1970s. He uses many methods to analyze what makes marriages work. Gottman interviews couples about the history of their marriage, their philosophy about marriage, and how they view their parents' marriages. He videotapes them talking to each other about how their day went and evaluates what they say about the good and bad times in their marriages. Gottman also uses physiological measures to record their heart rate, blood flow, blood pressure, and immune functioning moment by moment. He checks back with the couples every year to see how their marriage is faring. Gottman's research represents the most extensive assessment of marital relationships available. Currently, he and his colleagues are following 700 couples in seven studies.

Gottman argues that it is important to realize that love is not something magical and that through knowledge and effort couples can improve their relationship. In his research, Gottman has identified seven main practices that help marriages succeed:

- *Establish love maps.* Individuals in successful marriages have personal insights and detailed maps of each other's life and world. They aren't psychological strangers. In good marriages, partners are willing to share their feelings with each other. They use

John Gottman has conducted extensive research on what makes marriages work.  
Courtesy of The Gottman Institute, [www.gottman.com](http://www.gottman.com)

these “love maps” to express not only their understanding of each other but also their fondness and admiration.

- *Nurture fondness and admiration.* In successful marriages, partners sing each other’s praises. More than 90 percent of the time, when couples put a positive spin on their marriage’s history, the marriage is likely to have a positive future.
- *Turn toward each other instead of away.* In good marriages, spouses are adept at turning toward each other regularly. They see each other as friends. This friendship doesn’t keep arguments from occurring, but it can prevent differences from overwhelming the relationship. In these good marriages, spouses respect each other and appreciate each other’s point of view despite disagreements.
- *Let your partner influence you.* Bad marriages often involve one spouse who is unwilling to share power with the other. Although power-mongering is more common in husbands, some wives also show this trait. A willingness to share power and to respect the other person’s view is a prerequisite to compromising. One study revealed that equality in decision making was one of the main factors that predicted positive marriage quality (Amato, 2007).
- *Solve solvable conflicts.* Two types of problems occur in marriage: (1) perpetual and (2) solvable. Perpetual problems are the type that do not go away and may include disagreements about whether to have children and how often to have sex. Solvable problems can be worked out and may include such things as not helping each other reduce daily stresses and not being verbally affectionate. Unfortunately, more than two-thirds of marital problems fall into the perpetual category. Fortunately, marital therapists have found that couples often don’t have to solve their perpetual problems for the marriage to work. In his research, Gottman has found that to resolve conflicts, couples should start out with a soft rather than a harsh approach, try to make and receive “repair attempts,” regulate their emotions, compromise, and be tolerant of each other’s faults. Conflict resolution is not about one person making changes; it is about negotiating and accommodating each other.
- *Overcome gridlock.* One partner wants the other to attend church; the other is an atheist. One partner is a homebody; the other wants to go out and socialize a lot. Such problems often produce gridlock. Gottman believes the key to ending gridlock is not to solve the problem but to move from gridlock to dialogue and be patient.
- *Create shared meaning.* The more partners can speak candidly and respectfully with each other, the more likely it is that they will create shared meaning in their marriage. This also includes sharing goals with one’s spouse and working together to achieve each other’s goals.

In addition to Gottman’s view, other experts on marriage argue that such factors as forgiveness and commitment are important aspects of a successful marriage (Fincham, Stanley, & Beach, 2007). These factors function as self-repair processes in healthy relationships. For example, spouses may have a heated argument that has the potential to harm their relationship (Amato, 2007). After calming down, they may forgive each other and repair the damage.

Spouses with a strong commitment to each other may in times of conflict sacrifice their personal self-interest for the benefit of the marriage. Commitment especially becomes important when a couple is not happily married and can help them get through hard times with the hope that the future will involve positive changes in the relationship.

How important is the sexual aspect of a relationship in the couple’s marital satisfaction? A recent study in the second to fourteenth years of a marriage found that frequency of engaging in sexual intercourse was linked to a couple’s marital satisfaction, but that a satisfying sex life and a warm interpersonal relationship were more important (Schoenfeld & others, 2017).

For remarried couples, strategies for coping with the stress of living in a remarried family include the following (Bray, 2008; Sierra, 2015; Visher & Visher, 1989):

- *Have realistic expectations.* Allow time for loving relationships to develop, and look at the complexity of the stepfamily as a challenge to overcome.
- *Develop new positive relationships within the family.* Create new traditions and ways of dealing with difficult circumstances. Allocation of time is especially important because so many people are involved. The remarried couple needs to allot time alone for each other.

Unlike most approaches to helping couples, mine is based on knowing what makes marriages succeed rather than fail.

### developmental connection

#### Parenting

For most families, an authoritative parenting style is linked to more positive behavior on the part of children than authoritarian, indulgent, and neglectful styles. Connect to “Socioemotional Development in Early Childhood.”

- *Counter set relationship patterns or “ghosts.”* In prior relationships, spouses learned certain interaction patterns and these patterns can continue into the remarriage. Sometimes they have been called “ghosts” because they continue to haunt the individual unless he or she works to change them. For example, the husband in the newly created remarried family may have difficulty trusting his new wife because his previous wife cheated on him.

## BECOMING A PARENT

For many young adults, parental roles are well planned, coordinated with other roles in life, and developed with the parents’ economic situation in mind. For others, the discovery that they are about to become parents is a startling surprise. In either case, the prospective parents may have mixed emotions and idealistic illusions about having a child (Florsheim, 2014).

**Parenting Myths and Reality** The needs and expectations of parents have stimulated many myths about parenting (Williams, Sawyer, & Wahlstrom, 2017). These parenting myths include the following:

- The birth of a child will save a failing marriage.
- As a possession or extension of the parent, the child will think, feel, and behave as the parent did in his or her childhood.
- Having a child gives the parents a “second chance” to achieve what they wish they had achieved.
- Parenting is instinctual and requires no training.

Parenting requires a number of interpersonal skills and imposes emotional demands, yet there is little in the way of formal education for this task. Most parents learn parenting practices from their own parents, accepting some and discarding others. Unfortunately, when methods of parents are passed on from one generation to the next, both desirable and undesirable practices are perpetuated. Adding to the challenges of the task of parenting, husbands and wives may bring different parenting practices to the marriage. The parents, then, may struggle with each other about who has a better way to interact with a child.

Parent educators seek to help individuals to become better parents. To read about the work of one parent educator, see *Connecting with Careers*.

**Trends in Childbearing** As with marriage, the age at which people have children has been increasing (Baca Zinn, Eitzen, & Wells, 2016; Blieszner, 2018). In 2016, for the first time ever, more U.S. women were giving birth in their thirties than in their twenties (Centers for Disease Control and Prevention, 2017). In 2017, the average age for women giving birth was the highest it has ever been: 27 years of age. A national poll of 40- to 50-year-old U.S. women found that those with a master’s degree or higher first became mothers at 30; in comparison, the average age for women with a high school diploma was just 24 (Pew Research Center, 2015b).

As the use of birth control has become common, many individuals consciously choose when they will have children and how many children they will rear. The number of one-child families is increasing, and U.S. women overall are having fewer children. These childbearing changes are creating several trends:

- By giving birth to fewer children and reducing the demands of child care, women free up a significant portion of their life spans for other endeavors.
- Men are apt to invest a greater amount of time in fathering.
- Parental care is often supplemented by institutional care (child care, for example).

As more women show an increased interest in developing a career, they are not only marrying later but also having fewer children and having them later in life. What are some of the advantages of having children early or late? Some of the advantages of having children early (in the twenties) are that the parents are likely to have more physical energy (for example, they can cope better with such matters as getting up in the middle of the night with infants and waiting up until adolescents come home at night); the mother is likely to have fewer medical

problems with pregnancy and childbirth; and the parents may be less likely to build up expectations for their children, as do many couples who have waited many years to have children.

There are also advantages to having children later (in the thirties): The parents will have had more time to consider their goals in life, such as what they want from their family and career roles; the parents will be more mature and will be able to benefit from their life experiences to engage in more competent parenting; and the parents will be better established in their careers and have more income for child-rearing expenses.

## DEALING WITH DIVORCE

If a marriage doesn't work, what happens after divorce? Psychologically, one of the most common characteristics of divorced adults is difficulty trusting a new partner in a romantic relationship (Perelli-Harris & others, 2017). Following a divorce, though, people's lives can take diverse turns (Sbarra, Hasselmo, & Bourassa, 2015). In E. Mavis Hetherington's research, men and women took six common pathways after divorce (Hetherington & Kelly, 2002, pp. 98–108):

- *The enhancers.* Accounting for 20 percent of the divorced group, most were females who "grew more competent, well-adjusted, and self-fulfilled" following their divorce (p. 98). They were competent in multiple areas of life, showing a remarkable ability to bounce back from stressful circumstances and to create something meaningful out of problems.
- *The good-enoughs.* The largest group of divorced individuals, they were described as average people coping with divorce. They showed some strengths and some weaknesses, some successes and some failures. When they experienced a problem, they tried to solve it. Many of them attended night classes, found new friends, developed active social lives, and were motivated to get higher-paying jobs. However, they were not as good at planning and were less persistent than the enhancers. Good-enough women usually married men who educationally and economically were similar to their first husbands, often going into a new marriage that was not much of an improvement over the first one.
- *The seekers.* These individuals were motivated to find new mates as soon as possible. "At one year post-divorce, 40 percent of the men and 38 percent of the women had been classified as seekers. But as people found new partners or remarried, or became more secure or satisfied in their single life, this category shrank and came to be predominated by men" (p. 102).
- *The libertines.* People in this category often spent more time in singles bars and had more casual sex than their counterparts in the other divorce categories. However, by the end of the first year post-divorce, they often grew disillusioned with their sensation-seeking lifestyle and wanted a stable relationship.
- *The competent loners.* These individuals, who made up only about 10 percent of the divorced group, were "well-adjusted, self-sufficient, and socially skilled." They had a successful career,

# connecting development to life

## Coping and Adapting in the Aftermath of Divorce

Hetherington recommends the following strategies for divorced adults (Hetherington & Kelly, 2002):

- Think of divorce as a chance to grow personally and to develop more positive relationships.
- Make decisions carefully. The consequences of your decision making regarding work, lovers, and children may last a lifetime.
- Focus more on the future than the past. Think about what is most important for you going forward in your life, set some challenging goals, and plan how to reach them.

- Use your strengths and resources to cope with difficulties.
- Don't expect to be successful and happy in everything you do. "The road to a more satisfying life is bumpy and will have many detours" (p. 109).
- Remember that "you are never trapped by one pathway. Most of those who were categorized as defeated immediately after divorce gradually moved on to a better life, but moving onward usually requires some effort" (p. 109).

an active social life, and a wide range of interests. However, "unlike enhancers, competent loners had little interest in sharing their lives with anyone else" (p. 105).

- *The defeated.* Some of these individuals had problems before their divorce, and these problems increased after the breakup when "the added stress of a failed marriage was more than they could handle. Others had difficulty coping because divorce cost them a spouse who had supported them, or in the case of a drinking problem, restricted them" (p. 106).

To read about some guidelines for coping and adapting in the aftermath of divorce, see *Connecting Development to Life*.

### Review Connect Reflect

- What do you think would be the best age to have children? Why?

## 5 Gender and Communication Styles, Relationships, and Classification

Gender and Communication Styles

**LG5** Summarize the influence of gender on communication styles and relationships, and discuss gender classification.

Gender and Relationships

Gender Classification

In our discussion of children's socioemotional development, we described many aspects of gender development. Gender continues to be a very important aspect of adults' lives and a strong influence on their development. Here we discuss the communication styles of males

and females, how males and females relate to others, and how gender is classified in different ways, including the recent interest in transgender.

## GENDER AND COMMUNICATION STYLES

Stereotypes about differences in men's and women's attitudes toward communication and about differences in how they communicate with each other have spawned countless cartoons and jokes. Are the supposed differences real?

When Deborah Tannen (1990) analyzed the talk of women and men, she found that many wives complained about their husbands by saying that "He doesn't listen to me anymore" and "He doesn't talk to me anymore." Lack of communication, although high on women's lists of reasons for divorce, is mentioned much less often by men.

Communication problems between men and women may come in part from differences in their preferred ways of communicating. Tannen distinguishes *rapport talk* from *report talk*. **Rapport talk** is the language of conversation; it is a way of establishing connections and negotiating relationships. **Report talk** is talk that is designed to give information; this category of communication includes public speaking. According to Tannen, women enjoy rapport talk more than report talk, and men's lack of interest in rapport talk bothers many women. In contrast, men prefer to engage in report talk. Men hold center stage through verbal performances such as telling stories and jokes. They learn to use talk as a way to get and keep attention.

How extensive are gender differences in communication? Research has yielded somewhat mixed results. There is evidence of some gender differences (Anderson, 2006). One study of a sampling of students' e-mails found that people could guess the writer's gender two-thirds of the time (Thompson & Murachver, 2001). Another study revealed that women make 63 percent of phone calls and when talking to another woman stay on the phone longer (7.2 minutes) than men do when talking with other men (4.6 minutes) (Smoreda & Licoppe, 2000). However, meta-analyses suggest that overall gender differences in communication are small in both children and adults (Hyde, 2014; Leaper & Smith, 2004).

How are women's and men's communication styles different?

©Onoky/SuperStock

## GENDER AND RELATIONSHIPS

Beyond communication skills, what characterizes women's relationships? What characterizes men's relationships? What role does gender play in friendship?

**Women's Development** Tannen's analysis of women's preference for rapport talk suggests that women place a high value on relationships and focus on nurturing their connections with others. This view echoes some ideas of Jean Baker Miller (1986), who has been an important advocate for examining psychological issues from a female perspective. Miller argues that when researchers examine what women have been doing in life, a large part of it involves active participation in the development of others. In Miller's view, women often try to interact with others in ways that will foster the other person's development along many dimensions—emotional, intellectual, and social.

Most experts stress that it is important for women not only to maintain their competency in relationships but to be self-motivated, too (Brabek & Brabek, 2006). As Harriet Lerner (1989) concludes in her book *The Dance of Intimacy*, it is important for women to bring to their relationships nothing less than a strong, assertive, independent, and authentic self. She emphasizes that competent relationships are those in which the separate "I-ness" of both persons can be appreciated and enhanced while the partners remain emotionally connected with each other.

In sum, Miller, Tannen, and other gender experts such as Carol Gilligan note that women are more relationship-oriented than men are—and that this relationship orientation should be valued more highly in our culture than it currently is. Critics of this view of gender differences in relationships contend that it is too stereotypical (Hyde & Else-Quest, 2013). They argue that there is greater individual variation in the relationship styles of men and women than this view acknowledges.

In the field of the psychology of women, there is increased interest in women of color. To read about the work and views of one individual in this field, see the *Connecting with Careers* profile.

**rapport talk** The language of conversation; it is the way of establishing connections and negotiating relationships.

**report talk** Talk that is designed to give information; this category of communication includes public speaking.

## Cynthia de las Fuentes, College Professor and Counseling Psychologist

Cynthia de las Fuentes is a professor at Our Lady of the Lake University in San Antonio. She obtained her undergraduate degree in psychology and her doctoral degree in counseling psychology at the University of Texas in Austin. Among the courses she teaches are the psychology of women, Latino psychology, and counseling theories.

Dr. de las Fuentes is a past president of the Division of the Psychology of Women in the American Psychological Association.

"Many young women," she says, "take for granted that the women's movement has accomplished its goals—like equal pay for women, or reproductive rights—and don't realize that there is still work to be done." . . . She's interested in learning about people's intersecting identities, like female and Latina, and how the two work together (Winerman, 2005, pp. 66–67).

For more information about what college professors do, see the *Careers in Life-Span Development* appendix.

Cynthia de las Fuentes.  
Courtesy of Dr. Cynthia de las Fuentes

**Men's Development** The male of the species—what is he really like? What are his concerns? According to Joseph Pleck's (1995) role-strain view, male roles are contradictory and inconsistent. Men not only experience stress when they violate men's roles, they also are harmed when they act in accord with men's roles. Here are some of the areas where men's roles can cause considerable strain (Levant, 2001):

- *Health.* Men die 8 to 10 years earlier than women do. They have higher rates of stress-related disorders, alcoholism, car accidents, and suicide. Men are more likely than women to be the victims of homicide. In sum, the male role is hazardous to men's health.
- *Male-female relationships.* Too often, the male role involves expectations that men should be dominant, powerful, and aggressive and should control women. "Real men," according to many traditional definitions of masculinity, look at women in terms of their bodies, not their minds and feelings, have little interest in rapport talk and relationships, and do not consider women equal to men in work or many other aspects of life. Thus, the traditional view of the male role encourages men to disparage women, be violent toward women, and refuse to have equal relationships with women.
- *Male-male relationships.* Too many men have had too little interaction with their fathers, especially fathers who are positive role models. Nurturing and being sensitive to others have been considered aspects of the female role, not the male role. And the male role emphasizes competition rather than cooperation. All of these aspects of the male role have left men with inadequate positive, emotional connections with other males.

To reconstruct their masculinity in more positive ways, Ron Levant (2001) suggests that every man should (1) reexamine his beliefs about manhood, (2) separate out the valuable aspects of the male role, and (3) get rid of those parts of the masculine role that are destructive. All of these tasks involve becoming more "emotionally intelligent"—that is, becoming more emotionally self-aware, managing emotions more effectively, reading emotions better (one's own emotions and those of others), and being motivated to improve close relationships.

How can men improve their relationships?  
©Hero/Corbis/Glow Images

**Gender's Role in Friendships** As in the childhood and adolescent years, there are gender differences in adult friendship (Blieszner, 2016; Blieszner & Ogletree, 2017). Compared with men, women have more close friends and their friendships involve more self-disclosure and exchange of mutual support (Dow & Wood, 2006). Women are more likely to listen at

length to what a friend has to say and be sympathetic, and women have been labeled as “talking companions” because talk is so central to their relationships (Gouldner & Strong, 1987). Women’s friendships tend to be characterized not only by depth but also by breadth: Women share many aspects of their experiences, thoughts, and feelings (Blieszner, 2016). When female friends get together, they like to talk, but male friends are more likely to engage in activities, especially outdoors. Thus, the adult male pattern of friendship often involves keeping one’s distance while sharing useful information. Men are less likely than women to talk about their weaknesses with their friends, and men seek practical solutions to their problems rather than sympathy (Tannen, 1990). Also, adult male friendships are more competitive than those of women (Helgeson, 2012).

What are some characteristics of female-male friendships? Cross-gender friendships are more common among adults than children but less common than same-gender friendships in adulthood (Blieszner, 2016). Cross-gender friendships can present both opportunities and problems (Helgeson, 2012). The opportunities involve learning more about common feelings and interests and shared characteristics, as well as acquiring knowledge and understanding of beliefs and activities that historically have been typical of the other gender.

Problems can arise in cross-gender friendships because of different expectations. One problem that can plague an adult cross-gender friendship is unclear sexual boundaries, which can produce tension and confusion (Hart, Adams, & Tullett, 2016).

## GENDER CLASSIFICATION

Gender can be classified in multiple ways. In recent years, emphasis has been placed more on flexibility and equality in gender roles (Dean & Tate, 2017; Leaper, 2017; Mehta & Keener, 2017).

**Masculinity, Femininity, and Androgyny** In the mid-20th century, it was widely accepted that boys should grow up to be masculine (powerful, assertive, for example) and girls to be feminine (sensitive to others, caring, for example). In the 1970s, however, as both females and males became dissatisfied with the burdens imposed by their stereotypic roles, alternatives to femininity and masculinity were proposed. Instead of describing masculinity and femininity as a continuum in which more of one means less of the other, it was proposed that individuals could have both masculine and feminine traits.

This thinking led to the development of the concept of **androgyny**, the presence of positive masculine and feminine characteristics in the same person (Bem, 1977, 1993). The androgynous male might be assertive (masculine) and nurturing (feminine). The androgynous female might be powerful (masculine) and sensitive to others’ feelings (feminine). Measures have been developed to assess androgyny, such as the Bem Sex Role Inventory (Bem, 1997).

Gender experts such as Sandra Bem (1977, 1993) argue that androgynous individuals are more flexible, competent, and mentally healthy than their masculine or feminine counterparts. A recent study found that androgynous children had high self-esteem and few internalizing problems (Pauletti & others, 2017). To some degree, though, which gender-role classification is best may depend on the context involved. For example, in close relationships, feminine and androgynous orientations might be more desirable. One study found that girls and individuals high in femininity showed a stronger interest in caring than did boys and individuals high in masculinity (Karniol, Grosz, & Schorr, 2003). However, masculine and androgynous orientations might be more desirable in traditional academic and work settings because of the achievement demands in these contexts.

**Transgender** Recently, considerable interest has been directed toward a new category of gender classification, **transgender**, a broad term that refers to individuals who adopt a gender identity that differs from the one assigned to them at birth (Budge & Orovecz, 2017; Budge & others, 2018; Katz-Wise & others, 2018; King, 2017, 2019). For example, an individual may have female body but identify more strongly with being masculine than being feminine, or have a male body but identify more strongly with being feminine than masculine. A transgender identity of being born male but identifying with being a female is much more common than the reverse (Zucker, Lawrence, & Kreukels, 2016). Transgender persons also may not want to be labeled “he” or “she” but prefer a more neutral label such as “they” or “ze” (Scelfo, 2015).

How is adult friendship different among female friends, male friends, and cross-gender friends?

(Top to bottom) ©Stockbyte/PunchStock; ©Ilorente/Shutterstock; ©Ingram Publishing/age fotostock

**androgyny** The presence of positive masculine and feminine characteristics in the same person.

**transgender** A broad term that refers to individuals who adopt a gender identity that differs from the one assigned to them at birth.

What characterizes transgender individuals?

©Johnny Greig/Getty Images

Because of the nuances and complexities involved in such gender categorizations, some experts have recently argued that a better overarching umbrella term might be *trans* to identify a variety of gender identities and expressions different from the gender identity they were assigned at birth (Moradi & others, 2016). The variety of gender identities might include transgender, gender queer (also referred to as gender expansive, this broad gender identity category encompasses individuals who are not exclusively masculine or exclusively feminine), and gender nonconforming (individuals whose behavior/appearance does not conform to social expectations for what is appropriate for their gender). Another recently generated term, *cisgender*, can be used to describe individuals whose gender identity and expression match the gender identity assigned at birth (Moradi & others, 2016).

Transgender individuals can be straight, gay, lesbian, or bisexual. A recent research review concluded that transgender youth have higher rates of depression, suicide attempts, and eating disorders than their non-transgender peers (Connolly & others, 2016). Among the explanations for this higher rate of disorders are the distress of living in the wrong body and the discrimination and misunderstanding they experience as gender-minority individuals (Budge, Chin, & Minero, 2017).

Among individuals who identify themselves as transgender, the majority eventually adopt a gender identity in line with the body into which they were born (Byne & others, 2012; King, 2017, 2019). Some transgender individuals seek transsexual surgery to go from a male body to a female body or vice versa, but most do not. Some choose just to have hormonal treatments, such as biological females who use testosterone to enhance their masculine characteristics, or biological males who use estrogen to increase their feminine characteristics. Yet other transgender individuals opt for another, broader strategy that involves choosing a lifestyle that challenges the traditional view of having a gender identity that does not fit within one of two opposing categories (King, 2017, 2019; Savin-Williams, 2017). Because trans individuals experience considerable discrimination, it is important that society adopt a more welcoming and accepting attitude toward them.

## Review Connect Reflect

**LG5** Summarize the influence of gender on communication styles and relationships, and discuss gender classification.

### Review

- What are some differences in how women and men communicate?
- What are some important aspects of women's and men's roles in relationships?
- What are some different ways that gender can be classified?

### Connect

- In this section you read about many aspects of gender classification. How do you think the development of

sexuality that was discussed in "Physical and Cognitive Development in Adolescence" and "Physical and Cognitive Development in Early Adulthood" might influence an individual's gender classification?

### Reflect Your Own Personal Journey of Life

- How would you classify your own gender? What do you think influenced you to have that particular gender classification?

## topical connections *looking forward*

Middle adulthood is a time when individuals experience Erikson's seventh life-span stage, generativity versus stagnation. During this stage, it is important for middle-aged adults to contribute in meaningful ways to the next generation. In Levinson's theory, one of the key conflicts of middle age involves coping with the young-old polarity in life. Midlife crises are not as common as many people assume, but when they occur, negative life events usually are involved. A number of longitudinal studies of stability and change in adult development have been conducted, and recently it has been argued that stability peaks in middle adulthood. Affectionate love increases in middle age. Many middle-aged adults become grandparents. Middle-aged women especially play an important role in connecting generations.

## Socioemotional Development in Early Adulthood

### 1 Stability and Change from Childhood to Adulthood

Temperament

Attachment

LG1

Describe stability and change in temperament, and summarize adult attachment styles.

- Links between childhood temperament and adult personality can vary, depending on contexts in an individual's experience. A high activity level in early childhood is linked with being an outgoing young adult. Young adults show fewer mood swings, are more responsible, and engage in less risk taking than adolescents. In some cases, certain dimensions of temperament in childhood are linked with adjustment problems in early adulthood.
- Three adult attachment styles are secure attachment, avoidant attachment, and anxious attachment. Attachment styles in early adulthood are linked with a number of relationship patterns and developmental outcomes. For example, securely attached adults often show more positive relationship patterns than insecurely attached adults. Also, adults with avoidant and anxious attachment styles tend to be more depressed and have more relationship problems than securely attached adults.

### 2 Attraction, Love, and Close Relationships

Attraction

The Faces of Love

Falling Out of Love

LG2

Identify some key aspects of attraction, love, and close relationships.

- First impressions can be enduring. Familiarity precedes a close relationship. We like to associate with people who are similar to us. The principles of consensual validation and matching can explain this. Similarity in personality attributes may be especially important to a relationship's success. The criteria for physical attractiveness vary across cultures and historical time.
- The different types of love include friendship, romantic love, affectionate love, and consummate love. Friendship plays an important role in adult development, especially in providing emotional support. Romantic love, also called passionate love, includes passion, sexuality, and a mixture of emotions, not all of which are positive. Affectionate love, also called companionate love, usually becomes more important as relationships mature. Shaver proposed a developmental model of love and Sternberg a triarchic model of love (with dimensions of passion, intimacy, and commitment).
- The collapse of a close relationship can be traumatic, but for some individuals it results in happiness and personal development. For most individuals, falling out of love is painful and emotionally intense.

### 3 Adult Lifestyles

Single Adults

Cohabiting Adults

LG3

Characterize adult lifestyles.

- Being single has become an increasingly prominent lifestyle. Autonomy is one of its advantages. Intimacy, loneliness, and finding a positive identity in a marriage-oriented society are challenges faced by single adults.
- Cohabitation is an increasingly popular lifestyle, but researchers have found it is often linked to negative marital outcomes, although this link depends on the timing of cohabitation. Negative marital outcomes are more likely when cohabitation occurs prior to becoming engaged.

- The age at which individuals marry in the United States is increasing. Despite a decline in marriage rates, a large percentage of Americans still marry. The benefits of marriage include better physical and mental health and a longer life.
- The U.S. divorce rate increased dramatically in the middle of the twentieth century but began to decline in the 1980s. Divorce is complex and emotional. Both divorced men and women can experience loneliness, anxiety, and difficulty in forming new relationships.
- When adults remarry, they tend to do so rather quickly, with men remarrying sooner than women. Remarriage confers some benefits on adults but also some problems. Remarried families are less stable than families in first marriages, and remarried adults have a lower level of mental health than adults in first marriages, although remarriage improves adults' (especially women's) financial status. Stepfamilies come in many sizes and forms.
- One of the most striking findings about gay and lesbian couples is how similar their relationships are to heterosexual couples' relationships.

## 4 Marriage and the Family

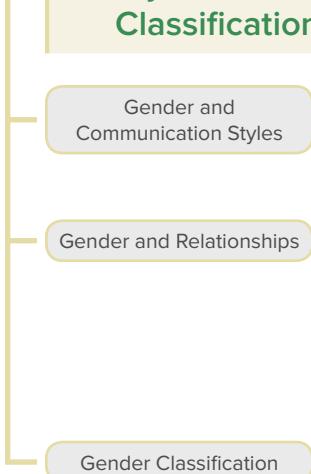

**LG4** Discuss making marriage work, parenting, and divorce.

- Gottman's research indicates that happily married couples establish love maps, nurture fondness and admiration, turn toward each other, accept the influence of the partner, solve solvable conflicts, overcome gridlock, and create shared meaning.
- Families are becoming smaller, and many women are delaying childbirth until they have become well established in a career. There are some advantages to having children earlier in adulthood and some advantages to having them later.
- Hetherington identified six pathways taken by people after divorce: enhancers, good-enoughs, seekers, libertines, competent loners, and the defeated. About 20 percent became better adjusted and more competent after the divorce.

## 5 Gender and Communication Styles, Relationships, and Classification

**LG5** Summarize the influence of gender on communication styles and relationships, and discuss gender classification.

- Tannen distinguishes between report talk, which many men prefer, and rapport talk, which many women prefer. Meta-analyses have found only small gender differences in overall communication, but recent research suggests some gender differences in specific aspects of gender communication, such as the way men and women use words.
- Some gender experts argue that women are more relationship-oriented than men. Critics argue that there is more individual variation in gender relationships. Many experts emphasize that it is important for women to retain their competence in relationships but also be self-motivated. The traditional male role involves strain, which takes a toll on men's health. The role also tends to discourage both equal relationships with females and positive emotional connections with other men. Gender differences also characterize adult friendships.
- In the mid-20th century, gender was classified as an individual being either masculine or feminine. In the 1970s, the concept of androgyny became popular and emphasized the importance of both positive masculine and feminine characteristics in the same individual. More recently, considerable attention has focused on a new gender category, transgender, which characterizes individuals whose gender identity is different from the one assigned to them at birth.

## Middle Adulthood

In middle adulthood, what we have been forms what we will be. For some of us, middle age is a foggy place, a time when we need to discover what we are running from and to and why. We compare our life with what we vowed to make it. In middle age, more time stretches behind us than before us, and some evaluations, however reluctant, have to be made. As the young-old polarity greets us with a special force, we need to join the daring of youth with the discipline of age in a way that does justice to both. As middle-aged adults, we come to sense that the generations of living things pass in a short while and, like runners, hand on the torch of life. This section consists of two chapters: “Physical and Cognitive Development in Middle Adulthood” and “Socioemotional Development in Middle Adulthood.”

# PHYSICAL AND COGNITIVE DEVELOPMENT IN MIDDLE ADULTHOOD

## chapter outline

### ① The Nature of Middle Adulthood

**Learning Goal 1** Explain how midlife is changing, and define middle adulthood

- Changing Midlife
- Defining Middle Adulthood

### ② Physical Development

**Learning Goal 2** Discuss physical changes in middle adulthood

- Physical Changes
- Health, Disease, Stress, and Control
- Mortality Rates
- Sexuality

### ③ Cognitive Development

**Learning Goal 3** Identify cognitive changes in middle adulthood

- Intelligence
- Information Processing

### ④ Careers, Work, and Leisure

**Learning Goal 4** Characterize career development, work, and leisure in middle adulthood

- Work in Midlife
- Career Challenges and Changes
- Leisure

### ⑤ Religion, Spirituality, and Meaning in Life

**Learning Goal 5** Explain the roles of religion, spirituality, and meaning in life during middle adulthood

- Religion, Spirituality, and Adult Lives
- Religion, Spirituality, and Health
- Meaning in Life

**O**ur perception of time depends on where we are in the life span. We are more concerned about time at some points in life than others. The rock group Pink Floyd, in their song “Time,” described how when we are young life seems longer and time passes more slowly, but when we get older, time seems to fly by so quickly.

In middle adulthood as well as late adulthood, individuals increasingly think about time-left-to-live instead of time-since-birth (Kotter-Gruhn & Smith, 2011; Rohr & others, 2017; Setterson, 2009). Middle-aged adults begin to look back to where they have been, reflecting on what they have done with the time they have had. They look toward the future in terms of how much time remains to accomplish what they hope to do with their lives. Older adults look backwards even more than middle-aged adults, not surprising given the shorter future in the life that they have. Also not surprisingly, given the many years they still have to live, emerging adults and young adults are more likely to look forward in time than backwards in time.

A recent research review examined subjective time in middle and late adulthood, including such components as future time perspective, personal goals, and autobiographical memories (Gabrian, Dutt, & Wahl, 2017). The review concluded that positive subjective time perceptions (such as an expanded view of the future, a focus on positive past and future life content, and favorable time-related evaluations) were linked to better health and well-being while negative subjective time perceptions were associated with lower levels of health and well-being.

Another aspect of time perception in middle age is the observation that time seems to speed by much faster as we get older. Talk to just about any middle-aged person and he or she will tell you that time does indeed fly by much faster than it did earlier in life. Why might this be?

One view is that for 10-year-olds, one year makes up 10 percent of their life so far and for 20-year-olds it makes up 5 percent of their life. However, for 50-year-olds, one year represents just one-fiftieth of their life, and thus the one year seems to fly by more quickly since it makes up a much smaller portion of the time they have lived.

A second view is that as middle age sets in, we begin to think more about the diminishing time we have left to live. Because of the fewer years we have left, we wish time would slow down. Because that can't happen, we perceive time to be flying by even faster. A common comment by someone who has reached 60 is, “Where did my fifties go? It seems like only yesterday I was 50 and now I’m 60.”

A third view is that new experiences slow down our perception of time, while repeated experiences make time seem to go faster. Younger people are more likely to have new experiences, and all of these new experiences slow down their perception of time. By contrast, when we reach middle age, more of our experiences are ones we already have had and thus we perceive time to be speeding by.

## topical connections *looking back*

Emerging adulthood, which occurs at approximately 18 to 25 years of age, is characterized by experimentation and exploration. Peak physical performance often occurs from about 19 to 26 years of age, but toward the latter part of early adulthood, a slowdown in physical performance is often apparent. Emerging adults have sexual intercourse with more individuals than young adults, but have sex less frequently. Thinking becomes more pragmatic and reflective in early adulthood than it was in adolescence. Career development is an important aspect of early adulthood, and work becomes a more central aspect of most young adults' lives.

## preview

When young adults look forward in time to what their lives might be like as middle-aged adults, too often they anticipate that things will go downhill. However, like all periods of the human life span, middle age usually holds both positive and negative features. In this first chapter on middle adulthood, we will discuss physical changes; cognitive changes; changes in careers, work, and leisure; as well as the importance of religion and meaning in life during middle adulthood. To begin, though, we will explore how middle age is changing.

### 1 The Nature of Middle Adulthood

LG1

Explain how midlife is changing, and define middle adulthood.

Changing Midlife

Defining Middle Adulthood

Is midlife experienced the same way today as it was 100 years ago? Is it different from what it was like just 25 years ago? How can middle adulthood be defined, and what are some of its main characteristics?

### CHANGING MIDLIFE

Many of today's 50-year-olds are in better shape, more alert, and more productive than their 40-year-old counterparts from a generation or two earlier. As more people lead healthier lifestyles and medical discoveries help to slow down the aging process, the boundaries of middle age are being pushed upward. It looks like middle age is starting later and lasting longer for increasing numbers of active, healthy, and productive people. A current saying is "60 is the new 40," implying that many 60-year-olds today are living a life that is as active, productive, and healthy as earlier generations did in their forties.

Questions such as, "To which age group do you belong?" and "How old do you feel?" reflect the concept of age identity. A consistent finding is that as adults become older their age identity is younger than their chronological age (Setterson & Trauten, 2009; Westerhof, 2009). One study found that almost half of the individuals 65 to 69 years of age considered themselves middle-aged (National Council on Aging, 2000). Another study discovered a similar pattern: Half of the 60- to 75-year-olds viewed themselves as being middle-aged (Lachman, Maier, & Budner, 2000). And a British survey of people over 50 years of age revealed that they perceived middle age to begin at 53 (Beneden Health, 2013). In this study, respondents said that being middle-aged is characterized by enjoying afternoon naps, groaning when you bend down, and preferring a quiet night in rather than a night out. Also, some individuals consider the upper boundary of midlife as the age at which they make the transition from work to retirement.

When Carl Jung studied midlife transitions early in the twentieth century, he referred to midlife as the afternoon of life (Jung, 1933). Midlife serves as an important preparation for late adulthood, "the evening of life" (Lachman, 2004, p. 306). But "midlife" came much earlier

How is midlife changing?  
©Colorblind Images/Getty Images

in Jung's time. In 1900 the average life expectancy was only 47 years of age; only 3 percent of the population lived past 65. Today, the average life expectancy is 79, and 15 percent of the U.S. population is older than 65 (U.S. Census Bureau, 2018). As a much greater percentage of the population lives to an older age, the midpoint of life and what constitutes middle age or middle adulthood are getting harder to pin down (Cohen, 2012).

In her book titled *In Our Prime: The Invention of Middle Age*, Patricia Cohen (2012) describes how middle age wasn't thought of as a separate developmental period until the mid-1800s and the term *midlife* wasn't in a dictionary until 1895. In Cohen's analysis, advances in health and more people living to older ages especially fueled the emergence of thinking about middle age. People today take longer to grow up and longer to age than in past centuries.

Compared with previous decades and centuries, an increasing percentage of the population is made up of middle-aged and older adults. In the past, the age structure of the population could be represented by a pyramid, with the largest percentage of the population in the childhood years. Today, the percentages of people at different ages in the life span are more similar, creating what is called the "rectangularization" of the age distribution (a vertical rectangle) (Himes, 2009; Schalkwijk & others, 2016). The rectangularization has been created by health advances that promote longevity, low fertility rates, and the aging of the baby-boom cohort (Moen, 2007).

Compared with late adulthood, far less research attention has been given to middle adulthood (Elliot & others, 2018; Lachman, Teshale, & Agrigoroaei, 2015). In a U.S. Census Bureau (2012) assessment, more than 102,713,000 people in the U.S. were 40 to 64 years of age, which accounts for 33.2 percent of the U.S. population. Given the large percentage of people in middle adulthood and the key roles that individuals in midlife play in families, the workplace, and the community, researchers need to give greater attention to this age period.

The portrait of midlife described so far here suggests that for too long the negative aspects of this developmental period have been overemphasized. Indeed, in a recent study, undergraduate college students were shown a computer generated graphic of a person identified as a younger adult, middle-aged adult, or older adult (Kelley, Soboroff, & Lovaglia, 2017). When asked which person they would choose for a work-related task, they selected the middle-aged adult most often. However, as will be seen in the following sections, it is important not to go too far in describing midlife positively. Many physical aspects decline in middle adulthood, and increased rates of health problems such as obesity and cardiovascular disease need to be considered in taking a balanced perspective on this age period (Kanesarajah & others, 2018).

## DEFINING MIDDLE ADULTHOOD

Although the age boundaries are not set in stone, we will consider **middle adulthood** to be the developmental period that begins at approximately 40 to 45 years of age and extends to about 60 to 65 years of age. For many people, middle adulthood is a time of declining physical skills and expanding responsibility; a period in which people become more conscious of the young-old polarity and the shrinking amount of time left in life; a point when individuals seek to transmit something meaningful to the next generation; and a time when people reach and maintain satisfaction in their careers. In sum, middle adulthood involves "balancing work and relationship responsibilities in the midst of the physical and psychological changes associated with aging" (Lachman, 2004, p. 305).

In midlife, as in other age periods, individuals make choices—selecting what to do, deciding how to invest time and resources, and evaluating what aspects of their lives they need to change (Hahn & Lachman, 2015). In midlife, "a serious accident, loss, or illness" may be a "wake-up call" and produce "a major restructuring of time and a reassessment" of life's priorities (Lachman, 2004, p. 310). And with an absence of seniority protections, many middle-aged adults experience unexpected job loss and/or are strongly encouraged to take early retirement packages.

The concept of gains (growth) and losses (decline) is an important one in life-span development (Lindenberger, 2014; Robinson & Lachman, 2017; Teshale & Lachman, 2016). Middle adulthood is the age period in which gains and losses as well as biological and sociocultural factors balance each other (Baltes, Lindenberger, & Staudinger, 2006). Although biological functioning declines in middle adulthood, sociocultural supports such as education, career, and relationships may peak in middle adulthood (Willis & Schaie, 2005). For example, neurobiological decline involves slow, gradual age-related decline in middle age, yet there is usually little or no negative consequences for effective functioning at work and completing the tasks of everyday living. Indeed, middle-aged adults may sense an urgency that now is the time to accomplish and do their best work.

Middle age is a mix of new opportunities and expanding resources accompanied by declines in physical abilities.

### developmental connection

#### Life-Span Perspective

There are four types of age: chronological, biological, psychological, and social. Connect to "Introduction."

**middle adulthood** The developmental period that begins at approximately 40 to 45 years of age and extends to about 60 to 65 years of age.

Margie Lachman and her colleagues (2015) recently described middle age as a pivotal period because it is a time of balancing growth and decline, linking earlier and later periods of development, and connecting younger and older generations.

Remember from our discussion in the “Introduction” chapter that individuals have not only a chronological age but also biological, psychological, and social ages. Some experts conclude that compared with earlier and later periods, middle age is influenced more heavily by sociocultural factors (Willis & Martin, 2005).

For many healthy adults, middle age is lasting longer than it did for previous generations. Indeed, an increasing number of experts on middle adulthood describe the age period of 55 to 65 as *late midlife* (Deeg, 2005). Compared with earlier midlife, late midlife is more likely to be characterized by “the death of a parent, the last child leaving the parental home, becoming a grandparent, the preparation for retirement, and in most cases actual retirement. Many people in this age range experience their first confrontation with health problems” (Deeg, 2005). Overall, then, although gains and losses may balance each other in early midlife, losses may begin to outnumber gains for many individuals in late midlife (Baltes, Lindenberger, & Staudinger, 2006).

Keep in mind, though, that midlife is characterized by individual variations (Lachman, Agrigoroaei, & Hahn, 2016; Robinson, Rickenbach, & Lachman, 2016). As life-span expert Gilbert Brim (1992) commented, middle adulthood is full of changes, twists, and turns; the path is not fixed. People move in and out of states of success and failure.

## Review Connect Reflect

**LG1** Explain how midlife is changing, and define middle adulthood.

### Review

- How is middle age today different from the way it was for past generations?
- How is middle adulthood defined, and what are some of its characteristics?

### Connect

- In this section you read about the “rectangularization” of age distribution in our current times being influenced

by, among other things, increasing longevity. What did you learn earlier about the history of human longevity?

### Reflect Your Own Personal Journey of Life

- How do you think you will experience (are experiencing or have experienced) middle age differently from your parents or grandparents?

## 2 Physical Development

**LG2**

Discuss physical changes in middle adulthood.

Physical Changes

Health, Disease, Stress, and Control

Mortality Rates

Sexuality

What physical changes characterize middle adulthood? How healthy are middle-aged adults? What are the main causes of death in middle age? How sexually active are individuals in middle adulthood?

### PHYSICAL CHANGES

Unlike the rather dramatic physical changes that occur in early adolescence and the sometimes abrupt decline in old age, midlife physical changes are usually more gradual. Although everyone experiences some downward physical change due to aging in middle adulthood, the rates of this aging vary considerably from one individual to another. Genetic makeup and lifestyle factors play important roles in determining whether chronic disease will appear and when (Kiviniemi & others, 2017; Pazoki & others, 2018). Middle age is a window through which we can glimpse later life while there is still time to engage in prevention and to influence some of the course of aging (Lachman, Teshale, & Agrigoroaei, 2015). Recent research has shown that a combination of multiple adaptive factors, such as positive health behaviors (physical exercise and sleep), a sense of control, social support and social connections, and emotion

Famous actor Sean Connery as a young adult in his twenties (top) and as a middle-aged adult in his fifties (bottom). What are some of the most outwardly noticeable signs of aging in middle adulthood?

Middle age is when your age starts to show around your middle.

—BOB HOPE

American Comedian, 20th Century

regulation helped to buffer declines in physical health and cognitive functioning in middle age (Robinson & Lachman, 2017).

Let's now explore some of the physical changes of middle age.

**Visible Signs** The most visible signs of physical changes in middle adulthood involve physical appearance. The first outwardly noticeable signs of aging usually are apparent by the forties or fifties. The skin begins to wrinkle and sag because of a loss of fat and collagen in underlying tissues (Cole & others, 2018; Czekalla & others, 2017). Small, localized areas of pigmentation in the skin produce age spots, especially in areas that are exposed to sunlight, such as the hands and face. Hair becomes thinner and grayer due to a lower replacement rate and a decline in melanin production. Fingernails and toenails develop ridges and become thicker and more brittle.

Since a youthful appearance is valued in many cultures, individuals whose hair is graying, whose skin is wrinkling, whose bodies are sagging, and whose teeth are yellowing may strive to make themselves look younger. Undergoing cosmetic surgery, dyeing hair, purchasing wigs, enrolling in weight reduction programs, participating in exercise regimens, and taking heavy doses of vitamins are common in middle age. Baby boomers have shown a strong interest in plastic surgery and Botox, which may reflect their desire to slow down the aging process (Harii & others, 2017; Lim & others, 2018).

**Height and Weight** Individuals lose height in middle age, and many gain weight (Lebenbaum & others, 2018; Yang & others, 2017a). On average, men from 30 to 50 years of age lose about one inch in height, then may lose another inch from 50 to 70 years of age (Hoyer & Roodin, 2009). The height loss for women can be as much as 2 inches from 25 to 75 years of age. Note that there are large variations in the extent to which individuals become shorter with aging. The decrease in height is due to bone loss in the vertebrae. On average, body fat accounts for about 10 percent of body weight in adolescence; it makes up 20 percent or more in middle age.

Obesity increases from early to middle adulthood (Lebenbaum & others, 2018; Nevalainen & others, 2017). In a national U.S. survey conducted in 2014, 40.2 percent of U.S. adults 40 to 59 years of age were classified as obese compared with 32.3 percent of younger adults (Centers for Disease Control and Prevention, 2014). Being overweight is a critical health problem in middle adulthood (Nevalainen & others, 2017; Wedell-Neergaard & others, 2018). For example, obesity increases the probability that an individual will suffer a number of other ailments, among them hypertension (abnormally high blood pressure), diabetes, and digestive disorders (Forrest, Leeds, & Ufelle, 2017; Jia, Hill, & Sowers, 2018; Kovesdy & others, 2017; Petrie, Guzik, & Touyz, 2018). A recent study revealed that an increase in weight gain from early adulthood to middle adulthood was linked to an increased risk of major chronic diseases and unhealthy aging (Zheng & others, 2017). A large-scale study found that being overweight or obese in middle age increases an individual's risk of dying earlier (Adams & others, 2006). More than 500,000 50- to 71-year-olds completed surveys about their height and weight, and the researchers examined the participants' death records across a 10-year period. Those who were overweight (defined as a body mass index, which takes into account height and weight, of 25 or more) at age 50 had a 20 to 40 percent higher risk of earlier death, whereas those who were obese (a body mass index of 30 or more) at age 50 had a 100 to 200 percent higher risk of premature death.

**Strength, Joints, and Bones** Maximum physical strength often is attained during the twenties. The term *sarcopenia* is given to age-related loss of muscle mass and strength (Landi & others, 2018; Picca & others, 2018). Muscle loss with age occurs at a rate of approximately 1 to 2 percent per year after age 50 (Marcell, 2003). A loss of strength especially occurs in the back and legs. Researchers are seeking to identify genes that are linked to the development of sarcopenia (Urano & Inoue, 2015). Obesity is a risk factor for sarcopenia (Albar-Almazan & others, 2018; Cruz-Jentoft & others, 2017). Recently, researchers have increasingly used the term "sarcopenic obesity" to describe individuals who have sarcopenia and are obese (Yang & others, 2017b; Xiao & others, 2018). One study found that sarcopenic obesity was linked to hypertension (Park & others, 2013). In a recent study sarcopenic obesity was associated with a 24 percent increase in risk for all-cause mortality, with a higher risk for men than for women (Tian & Xu, 2016). And a research review concluded that weight management and resistance

training were the best strategies to slow down the decline of muscle mass and muscle strength (Rolland & others, 2011).

Peak functioning of the body's joints usually occurs in the twenties. The cushions for the movement of bones (such as tendons and ligaments) become less efficient in middle adulthood, a time when many individuals experience joint stiffness and more difficulty in movement.

Maximum bone density occurs by the mid- to late thirties, after which there is a progressive loss of bone. The rate of this bone loss begins slowly but accelerates with further aging (Locquet & others, 2018). Women lose bone mass twice as fast as men do. By the end of midlife, bones break more easily and heal more slowly (de Villiers, 2018; Gulsahi, 2015). A recent study found that greater intake of fruits and vegetables was linked to increased bone density in middle-aged and older adults (Qiu & others, 2017).

**Vision and Hearing** Accommodation of the eye—the ability to focus and maintain an image on the retina—experiences its sharpest decline between 40 and 59 years of age. In particular, middle-aged individuals begin to have difficulty viewing close objects.

The eye's blood supply also diminishes, although usually not until the fifties or sixties. The reduced blood supply may decrease the visual field's size and account for an increase in the eye's blind spot. At 60 years of age, the retina receives only one-third as much light as it did at 20 years of age, mostly because of the reduced size of the pupil (Scialfa & Kline, 2007).

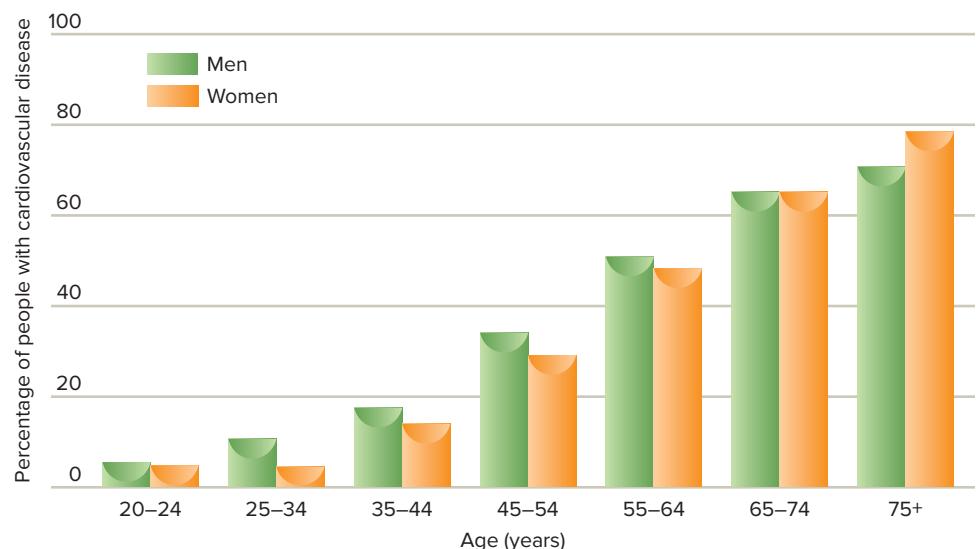

Hearing also can start to decline by age 40. Auditory assessments indicate that hearing loss occurs in up to 50 percent of individuals 50 years and older (Fowler & Leigh-Paffenroth, 2007). Sensitivity to high pitches usually declines first; the ability to hear low-pitched sounds does not seem to decline much in middle adulthood. Men usually lose their sensitivity to high-pitched sounds sooner than women do. However, this gender difference might be due to men's greater exposure to noise in occupations such as mining, automobile work, and so on.

Researchers are identifying new possibilities for improving the vision and hearing of people as they age (Uemura, 2018; Wingfield & Lash, 2016). One strategy involves better control of glare or background noise (Richter & others, 2018). Laser surgery and implantation of intraocular lenses have become routine procedures for correcting vision in middle-aged adults (Arba-Mosquera, Vinciguerra, & Verma, 2018). In addition, recent advances in hearing aids have dramatically improved hearing for many individuals (Courtois & others, 2018). However, even with the advent of technologically sophisticated hearing devices, many people don't always wear them, or they wear them incorrectly.

**Cardiovascular System** Midlife is a time when high blood pressure and high cholesterol often take adults by surprise. Cardiovascular disease increases considerably in middle age (Kanesarajah & others, 2018; Mok & others, 2018), as indicated in Figure 1.

The level of cholesterol in the blood increases during the adult years and in midlife begins to accumulate on the artery walls, increasing the risk of cardiovascular disease (Choi & Lee, 2017; Mok & others, 2018). The type of cholesterol in the blood, however, influences its effect (Pirillo & others, 2018; Talbot & others, 2018). Cholesterol comes in two forms: LDL (low-density lipoprotein) and HDL (high-density lipoprotein). LDL is often referred to as "bad" cholesterol because when the level of LDL is too high, it sticks to the lining of blood vessels, which can lead to arteriosclerosis (hardening of the arteries). HDL is often referred to as "good" cholesterol because when it is high and LDL is low, the risk of cardiovascular disease is lower.

High blood pressure (hypertension), too, often begins to appear for many individuals in their forties and fifties (Mrowka, 2017). At menopause, a woman's blood pressure rises sharply and usually remains above that of a man through life's later years (Di Giosia & others, 2018; Taler, 2009). One study found that uncontrolled hypertension can damage the brain's structure

**FIGURE 1**  
**THE RELATION OF AGE AND GENDER TO CARDIOVASCULAR DISEASE.** Notice the sharp increase in cardiovascular disease in middle age.

Members of the Masai tribe in Kenya, Africa, can stay on a treadmill for a long time because of their active lives. The extremely low incidence of heart disease in the Masai tribe is likely linked to their energetic lifestyle.

Courtesy of The Family of Dr. George V. Mann

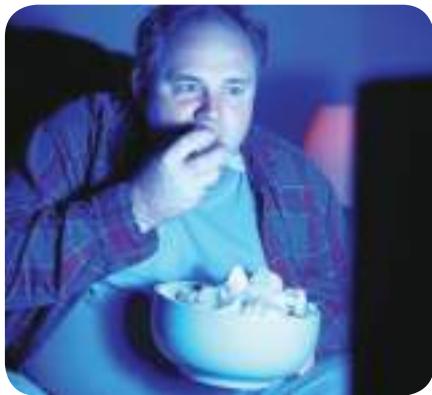

and function as early as the late thirties and early forties (Maillard & others, 2012). In this study, structural damage to the brain's white matter (axons) and decreased volume of gray matter (cell bodies and dendrites) occurred for individuals who had hypertension (systolic number above 140 and diastolic number above 90). Another study revealed that hypertension in middle age was linked to risk of cognitive impairment in late adulthood (23 years later) (Virta & others, 2013).

Exercise, weight control, and a diet rich in fruits, vegetables, and whole grains can often help to stave off many cardiovascular problems in middle age (de Gregorio, 2018; Kim & others, 2017). In a recent study, a high level of physical activity was associated with a lower risk of cardiovascular disease in the three weight categories studied (normal, overweight, and obese) (Carlsson & others, 2016). Also, although cholesterol levels are influenced by heredity, LDL can be reduced and HDL increased by eating food that is low in saturated fat and cholesterol and by exercising regularly (Koba & others, 2016). One study of postmenopausal women revealed that 12 weeks of aerobic exercise training improved their cardiovascular functioning (O'Donnell, Kirwan, & Goodman, 2009).

The good news is that deaths due to cardiovascular disease have been decreasing in the United States since the 1970s. Why is this so? Advances in medications to lower blood pressure and cholesterol in high-risk individuals have been major factors in reducing deaths due to cardiovascular disease (Svatikova & Kopecky, 2017; Talbot & others, 2018). Regular exercise and healthy eating habits also have considerable benefits in preventing cardiovascular disease (Kim & others, 2017). A recent national study confirmed that moderate-to-vigorous physical activity (such as running, swimming, bicycling) on a regular basis was linked to reduced rates of all-cause mortality, especially for men (Loprinzi, 2015a). Another recent study found that having an unhealthy diet was a strong predictor of cardiovascular disease (Menotti & others, 2015). Also, a recent Chinese study revealed that men and women who gained an average of 22 pounds or more from 20 to 60 years of age had an increased risk of hypertension and cholesterol, as well as elevated triglyceride levels in middle age (Zhou & others, 2018). And risk factors for cardiovascular disease in middle adulthood can show up even earlier in development. For example, a recent study indicated that a healthy diet in adolescence was linked to a lower risk of cardiovascular disease in middle-aged women (Dahm & others, 2018). Socioeconomic status (SES) factors also play a role in cardiovascular disease in middle adulthood. A 32-year study found that middle-aged individuals who continued to have a lower SES through early adulthood and into middle adulthood were more likely to have a lower level of cardiovascular health than their counterparts who experienced an improvement in their SES status across the study years (Savelieva & others, 2017).

As reflected in the research we have just described, the American Heart Association has proposed Life's Simple 7—a list of things people can do to improve their cardiovascular health: (1) manage blood pressure, (2) control cholesterol, (3) reduce blood sugar, (4) get active, (5) eat better, (6) lose weight, and (7) quit smoking. In a recent study, optimal Life's Simple 7 at middle age was linked to better cardiovascular health recovery following a heart attack later in life (Mok & others, 2018).

An increasing problem in middle and late adulthood is **metabolic syndrome**, a condition characterized by hypertension, obesity, and insulin resistance (Ladeiras-Lopes & others, 2018; Mora-Rodriguez & others, 2017). Researchers have found that chronic stress exposure is linked to metabolic syndrome (Bergmann & others, 2017). Metabolic syndrome often leads to the development of diabetes and cardiovascular disease (Masmiquel & others, 2016; Savadatti & others, 2018). Weight loss and exercise are strongly recommended as part of the treatment of metabolic syndrome (Palmnas & others, 2018; Ross, 2017).

What characterizes metabolic syndrome?

©Ryan McVay/Getty Images

**metabolic syndrome** A condition characterized by hypertension, obesity, and insulin resistance. Metabolic syndrome often leads to the onset of diabetes and cardiovascular disease.

**Lungs** There is little change in lung capacity through most of middle adulthood for many individuals. However, at about age 55, the proteins in lung tissue become less elastic. This change, combined with a gradual stiffening of the chest wall, decreases the lungs' capacity to shuttle oxygen from the air people breathe to the blood in their veins. The lung capacity of individuals who are smokers drops precipitously in middle age, but if the individuals quit smoking, their lung capacity improves, although not to the level of individuals who have never smoked.

Exercise is linked to better lung functioning and a lower risk of developing lung cancer (Strookappe & others, 2015). In one study, more than 17,000 men were given a cardiovascular fitness assessment at 50 years of age (Lakoski & others, 2013). Subsequent analysis of Medicare claims and deaths found that the risk of being diagnosed with lung cancer was reduced by 68 percent for men who were the most fit compared with those who were the least fit. A

longitudinal study also found that increased cardiorespiratory fitness from early adulthood to middle adulthood was linked to less decline in lung health over time (Benck & others, 2017).

**Sleep** The average American adult gets just under seven hours of sleep a night. How much sleep do adults need to function optimally the next day? An increasing number of experts note that eight hours of sleep or more per night are necessary for optimal performance the next day. These experts argue that many adults have become sleep deprived (McKenna & others, 2013). Work pressures, school pressures, family obligations, and social obligations often lead to long hours of wakefulness and irregular sleep/wake schedules (Soderstrom & others, 2012). Habitual sleep deprivation is linked to morbidity, especially among people with cardiovascular disease (Grandner & others, 2013). A recent Korean study found that these factors were linked to sleep problems in middle age: unemployment, being unmarried, currently being a smoker, lack of exercise, having irregular meals, and frequently experiencing stressful events (Yoon & others, 2015). In a recent study of young and middle-aged adults, females had more severe sleep problems than males did (Rossler & others, 2017). However, in this study the good news is that a majority of individuals (72 percent) reported no sleep disturbances (Rossler & others, 2017).

Some aspects of sleep become more problematic in middle age (Baker & others, 2018; Muller & others, 2017). The total number of hours slept usually remains the same as in early adulthood, but beginning in the forties, wakeful periods are more frequent and there is less of the deepest type of sleep. The amount of time spent lying awake in bed at night begins to increase in middle age, and this can produce a feeling of being less rested in the morning. Sleep-disordered breathing and restless legs syndrome become more prevalent in middle age (Stehlik & others, 2018). Further, a recent study revealed that poor sleep quality in middle adulthood was linked to cognitive decline (Waller & others, 2016). Sleep problems in midlife are more common among individuals who use a higher number of prescription and nonprescription drugs, are obese, have cardiovascular disease, or are depressed (Muller & others, 2017). And a recent study indicated that perceiving oneself as feeling older predicted an increase in sleep difficulties in middle age over time (Stephan & others, 2017).

## HEALTH, DISEASE, STRESS, AND CONTROL

In middle adulthood, the frequency of accidents declines and individuals are less susceptible to colds and allergies than in childhood, adolescence, or early adulthood. Indeed, many individuals live through middle adulthood without having a disease or persistent health problem. However, disease and persistent health problems become more common in middle adulthood for some individuals (Koyanagi & others, 2018).

**Chronic disorders** are characterized by a slow onset and a long duration. Chronic disorders are rare in early adulthood, increase in middle adulthood, and become common in late adulthood. Chronic disorders account for 86 percent of total health care spending in the United States (Qin & others, 2015). Overall, arthritis is the leading chronic disorder in middle age, followed by hypertension, but the frequency of chronic disorders in middle age varies by gender. Men have a higher incidence of fatal chronic conditions (such as coronary heart disease, cancer, and stroke); women have a higher incidence of nonfatal ones (such as arthritis, varicose veins, and bursitis).

About 50 percent of U.S. adults have one chronic health condition, and the prevalence of multiple (two or more) chronic health conditions increased from 21.8 percent in 2001 to 25.5 percent in 2012 (Qin & others, 2015). In a recent analysis, adults with arthritis as one of their multiple chronic conditions had more adverse outcomes (social participation restriction, serious psychological distress, and work limitations) than their counterparts who had multiple chronic conditions but did not have arthritis (Qin & others, 2015).

**Stress and Disease** Stress is increasingly identified as a factor in many diseases (Yu & others, 2018). The cumulative effect of stress often takes a toll on the health of individuals by the time they reach middle age. David Almeida and his colleagues (2011) conclude that chronic stress or prolonged exposure to stressors can have damaging effects on physical functioning, including an unhealthy overproduction of corticosteroids such as cortisol. Chronic stress can interfere with immune functioning, and this stress is linked to disease not only through the immune system but also through cardiovascular factors (Fali, Vallet, & Sauce, 2018; Sin & others, 2016).

**chronic disorders** Disorders that are characterized by slow onset and long duration. They are rare in early adulthood, increase during middle adulthood, and become common in late adulthood.

## developmental connection

### Stress

Recently, a variation of hormonal stress theory has emphasized a decline in immune system functioning as an important contributor to lower resistance to stress in older adults. Connect to “Physical Development in Late Adulthood.”

An important aspect of the link between stress and disease involves stress hormones. One hormone in particular, *cortisol*, has been labeled the stress hormone because elevated cortisol levels are linked to physical health problems such as lower immune system functioning and higher blood pressure, cholesterol, and cardiovascular disease, as well as to higher levels of mental health problems such as anxiety and depressive disorders (Leonard, 2018; Wichmann & others, 2017). A recent study of men and women from 21 to 55 years of age found that married individuals had lower cortisol levels than either their never-married or previously married counterparts (Chin & others, 2017).

How individuals react to stressors is linked to health outcomes. In one study, how people reacted to daily stressors in their lives was linked to future chronic health problems (Piazza & others, 2013). Also, in a recent study, adults who did not maintain positive affect when confronted with minor stressors in everyday life had elevated levels of IL-6, an inflammation marker (Sin & others, 2015). And in another recent study, a greater decrease in positive affect in response to daily stressors was associated with earlier death (Mroczeck & others, 2015).

**The Immune System and Stress** The immune system keeps us healthy by recognizing foreign materials such as viruses, tumors, and harmful bacteria and then destroying them (Hughes, Connor, & Harkin, 2018; Yousefi & others, 2017). Immune system functioning becomes less effective with normal aging (Fali, Vallet, & Sauce, 2018; Liang & others, 2017).

The immune system’s machinery consists of billions of white blood cells located in the circulatory system. The number of white blood cells and their effectiveness in killing viruses or harmful bacteria are related to stress levels. When a person is under stress, viruses and bacteria are more likely to multiply and cause disease. One study in young and middle-aged adults revealed that persistently unemployed individuals had lower natural killer (NK) cell levels than their previously unemployed counterparts who became reemployed (Cohen & others, 2007). NK cells are a type of white blood cell that is more likely to be present in low-stress circumstances (see Figure 2). Lower levels of NK cells in stressful situations indicate a weakened immune system (Mehta & others, 2018; Messaoudene & others, 2017). Another study indicated aerobic fitness was related to the presence of a lower level of senescent T cells (prematurely aging cells that result from persistent immune activation) (Spielmann & others, 2011).

Janet Kiecolt-Glaser and her colleagues have conducted many studies that further clarify the roles of stress and immune system functioning in a number of contexts:

- Failures in close relationships (divorce, separation, and marital distress) reduce immune system functioning, especially when spouses have hostile interactions, with the effects stronger in women than men (Jaremka & others, 2013a, 2016; Kiecolt-Glaser & others, 2015; Kiecolt-Glaser & Wilson, 2017).
- Having positive social ties can boost immune system functioning, and lack of social ties, especially prolonged loneliness, can increase stress and decrease immune system functioning (Fagundes & others, 2016; Jaremka, Derry, & Kiecolt-Glaser, 2016; Kiecolt-Glaser & Wilson, 2017; Jaremka & others, 2013b).
  - Burdensome caregiving for a family member with a progressive illness reduces immune system functioning (Bennett, Fagundes, & Kiecolt-Glaser, 2016).
  - Chronic and acute stress increase the inflammation associated with age-related diseases such as cardiovascular disease, type 2 diabetes, arthritis, and some cancers.
  - Stress-reducing activities such as yoga, relaxation, and hypnosis have positive influences on immune system functioning (Derry & others, 2015; Kiecolt-Glaser & others, 2014).

Sheldon Cohen and his colleagues have extensively studied immunity and susceptibility to infectious disease (Cohen & Janicki-Deverts, 2012; Cohen, Janicki-Deverts, & Doyle, 2015; Cohen & Shachar, 2012; Cohen & others, 2012, 2013, 2015). They have found that factors such as stress, emotion, and lack of social support compromise people’s immune system functioning in ways that alter their bodies’ ability to fight off disease.

**Stress and the Cardiovascular System** Stress and negative emotions can affect the development and course of cardiovascular disease by

altering underlying physiological processes (Mathews & others, 2018). Sometimes, though, the link between stress and cardiovascular disease is indirect. For example, people who live in a chronically stressed condition, such as persistent poverty, are more likely to take up smoking, start overeating, and avoid exercising (Boylan, Cundiff, & Matthews, 2018; Brooks & others, 2018). All of these stress-related behaviors are linked to the development of cardiovascular disease (Albert & others, 2017).

**Control** Although many diseases increase in middle age, having a sense of control is linked to many aspects of health and well-being (Lachman, Agrigoroaei, & Hahn, 2016; Robinson & Lachman, 2017). Researchers have found that having a sense of control peaks in midlife and then declines in late adulthood (Drewelies & others, 2017; Lachman, 2006; Lachman, Rosnick, & Rocke, 2009). However, in any adult age period, there is a wide range of individual differences in beliefs about control. Margie Lachman and her colleagues (2015, 2016) argue that having a sense of control in middle age is one of the most important modifiable factors in delaying the onset of diseases in middle adulthood and reducing the frequency of diseases in late adulthood. Recent research indicates that control can have long-term consequences for health and even mortality risk (Robinson & Lachman, 2017; Turiano & others, 2014).

Increasing evidence indicates there is a bidirectional link between perceived control and health (Robinson & Lachman, 2017). For example, in one study, greater perceived control predicted a higher level of well-being and better health, while a higher level of well-being and better health also predicted greater perceived control across a 16-year period (Infurna & others, 2013).

## MORTALITY RATES

Infectious disease was the main cause of death until the middle of the twentieth century. As infectious disease rates declined and more individuals lived through middle age, rates of chronic disorders increased. Chronic diseases are now the main causes of death for individuals in middle adulthood.

In middle age, many deaths are caused by a single, readily identifiable condition, whereas in old age, death is more likely to result from the combined effects of several chronic conditions (Pizza & others, 2011). For many years heart disease was the leading cause of death in middle adulthood, followed by cancer; however, since 2005 more individuals 45 to 64 years of age in the United States died of cancer, followed by cardiovascular disease (Centers for Disease Control and Prevention, 2015; Kochanek & others, 2011). The gap between cancer and the second leading cause of death widens as individuals age. In 2013, about 46,000 45- to 54-year-olds died of cancer and about 35,000 died of cardiovascular disease; about 113,000 55- to 64-year-olds died of cancer and 73,000 died of cardiovascular disease (Centers for Disease Control and Prevention, 2015). Men have higher mortality rates than women for all of the leading causes of death (Kochanek & others, 2011).

## SEXUALITY

What kinds of changes characterize the sexuality of women and men as they go through middle age? **Climacteric** is a term that is used to describe the midlife transition in which fertility declines. Let's explore the substantial differences in the climacteric experienced by women and men.

**Menopause** Menopause is the time in middle age, usually during the late forties or early fifties, when a woman's menstrual periods cease. The average age at which U.S. women have their last period is 51 (Wise, 2006). However, there is a large variation in the age at which menopause occurs—from 39 to 59 years of age. Later menopause is linked with increased risk of breast cancer (Mishra & others, 2009).

The timing of menarche, a girl's first menstruation, has significantly decreased since the mid-nineteenth century, occurring as much as four years earlier in some countries (Susman & Dorn, 2013). Has there been a similar earlier onset in the occurrence of menopause? No, there hasn't been a corresponding change in menopause, and there is little or no correlation between ages at menarche and the onset of menopause (Gosden, 2007).

**climacteric** The midlife transition during which fertility declines.

**menopause** Cessation of a woman's menstrual periods, usually during the late forties or early fifties.

Mosuo women, who live in a matriarchal tribe in southern China and have fewer negative menopausal symptoms than women in many cultures.

*Perimenopause* is the transitional period from normal menstrual periods to no menstrual periods at all, which often takes up to 10 years. Perimenopause usually occurs during the forties but can occur in the thirties (Honour, 2018). One study of 30- to 50-year-old women found that depressed feelings, headaches, moodiness, and palpitations were the perimenopausal symptoms that these women most frequently discussed with health-care providers (Lyndaker & Hulton, 2004). Lifestyle factors such as whether women are overweight, smoke, drink heavily, feel depressed, or exercise regularly during perimenopause influence aspects of their future health such as whether they develop cardiovascular disease or chronic illnesses (Bacon, 2017; Honour, 2018). A recent study found that the more minutes per week that women exercised during the menopausal transition, the lower their perceived stress was (Guerin & others, 2018).

In menopause, production of estrogen by the ovaries declines dramatically, and this decline produces uncomfortable symptoms in some women—“hot flashes,” nausea, fatigue, and rapid heartbeat, for example (Chiaramonte, Ring, & Locke, 2017; Islam & others, 2017; Noble, 2018). However, cross-cultural studies reveal variations in the menopause experience (Hinrichsen & others, 2014; Sievert, 2014). For example, hot flashes are uncommon in Mayan women (Beyene, 1986). Asian women report fewer hot flashes than women in Western societies (Payer, 1991). In a recent study in China, Mosuo women (Mosuo is a matriarchal tribe in southern China where women have the dominant role in society, don’t marry, and can take on as many lovers as they desire) had fewer negative menopausal symptoms, higher self-esteem, and better family support than Han Chinese women (the majority ethnic group in China) (Zhang & others, 2016). It is difficult to determine the extent to which these cross-cultural variations are due to genetic, dietary, reproductive, or cultural factors.

For most women, menopause overall is not the highly negative experience it was once thought to be (Brown & others, 2018; Henderson, 2011). Few women have severe physical or psychological problems related to menopause. In fact, a research review concluded that there is no clear evidence that depressive disorders occur more often during menopause than at other times in a woman’s reproductive life (Judd, Hickey, & Bryant, 2012).

However, the loss of fertility is an important marker for women—it means that they have to make final decisions about having children. Women in their thirties who have never had children sometimes speak about being “up against the biological clock” because they cannot postpone choices about having children much longer.

Until recently, hormone replacement therapy was often prescribed as treatment for unpleasant side effects of menopause. *Hormone replacement therapy (HRT)* augments the declining levels of reproductive hormone production by the ovaries (Andersson, Borgquist, & Jirstrom, 2018; Langer, 2017; Lobo, 2017). HRT can consist of various forms of estrogen, usually in combination with a progestin. In a recent position statement by leading experts of the North American Menopause Society (2017), the following conclusions were reached about HRT:

- Hormone replacement therapy is most favorable in reducing negative menopausal symptoms and reducing bone loss or fracture for women 60 years and younger who are within 10 years of menopausal onset.
- Hormone replacement therapy is less favorable for women who are more than 10 or more years from menopausal onset or are 60 years and older because of greater risk for cardiovascular disease and Alzheimer disease.

Further, research indicates that hormone replacement therapy is linked to a slightly higher risk of breast cancer and the longer HRT is taken, the greater the risk of breast cancer (American Cancer Society, 2018; Breastcancer.org, 2018). The current consensus is that HRT increases the risk of breast cancer in women (Breastcancer.org, 2018).

The National Institutes of Health recommends that women who have not had a hysterectomy and who are currently taking hormones consult with their doctor to determine whether they should continue the treatment. If they are taking HRT for short-term relief of menopausal symptoms, the benefits may outweigh the risks (Langer, 2017; Santen & others, 2014). Many middle-aged women are seeking alternatives to HRT such as regular exercise, dietary supplements, herbal remedies, relaxation therapy, mindfulness training, acupuncture, and nonsteroidal medications (Goldstein, 2017; Lund & others, 2018; Nasiri, 2015; Woyka,

2017). One study revealed that in sedentary women, aerobic training for 6 months decreased menopausal symptoms, especially night sweats, mood swings, and irritability (Moilanen & others, 2012). Another study found that yoga improved the quality of life of menopausal women (Reed & others, 2014).

**Hormonal Changes in Middle-Aged Men** Do men go through anything like the menopause that women experience? In other words, is there a male menopause? During middle adulthood, most men do not lose their capacity to father children, although there usually is a modest decline in their sexual hormone level and activity (Blumel & others, 2014; Janini & Nappi, 2018). They experience hormonal changes in their fifties and sixties, but nothing like the dramatic drop in estrogen that women experience. Testosterone production begins to decline about 1 percent a year during middle adulthood, and sperm count usually declines slowly, but men do not lose their fertility in middle age. The term *male hypogonadism* is used to describe a condition in which the body does not produce enough testosterone (Mayo Clinic, 2018).

Recently, there has been a dramatic surge of interest in *testosterone replacement therapy (TRT)* (Gilbert & others, 2017; Ismaeel & Wang, 2017; Sansone & others, 2017; Tyagi & others, 2017). For many decades, it was thought that TRT increased the risk of prostate cancer; however, recent studies and research reviews indicate that is not the case (Debruyne & others, 2017; Yassin & others, 2017). Recent research indicates that TRT can improve sexual functioning, muscle strength, and bone health (Gray, McHale, & Carre, 2017; Hackett & others, 2017; Hassan & Barkin, 2016; Kaya & others, 2017; Mayo Clinic, 2017; Williams & Cho, 2017). A recent study found that TRT was associated with increased longevity in men with a low level of testosterone (Comhaire, 2016). Another recent study indicated that TRT-related benefits in quality of life and sexual function were maintained for 36 months after initial treatment (Rosen & others, 2017). Also, recent research has revealed that testosterone replacement therapy is associated with a lower incidence of having a heart attack or a stroke, as well as a reduction in all-cause mortality (Cheetham & others, 2017; Jones & Kelly, 2018; Sharma & others, 2015). Two studies found that TRT improved older men's sexual function as well as their mood (Miner & others, 2013; Okada & others, 2014). Further, another study found that a higher testosterone level was linked to better episodic memory in middle-aged males (Panizzon & others, 2014).

**Erectile dysfunction (ED)** (difficulty attaining or maintaining penile erection) affects approximately 50 percent of men 40 to 70 years of age and 75 percent of men over 70 years of age (Mola, 2015). Low testosterone levels can contribute to erectile dysfunction (Hackett & Kirby, 2018). Smoking, diabetes, hypertension, elevated cholesterol levels, obesity, depression, and lack of exercise also are associated with erectile problems in middle-aged men (Furukawa & others, 2017; Gur & others, 2017; Kouidrat & others, 2017; Rakovac Tisdall & others, 2018; Schulster, Liang, & Najari, 2017; Sgro & Di Luigi, 2017). The main treatment for men with erectile dysfunction has not focused on TRT but on Viagra and similar drugs such as Levitra and Cialis (Bennett, 2018; Gesser-Edelsburg & Hijazi, 2018; Goldstein, Stecher, & Carlsson, 2017; Melehan & others, 2018; Ozcan & others, 2018; Peng & others, 2017). Viagra works by allowing increased blood flow into the penis, which produces an erection. Its success rate is in the 60 to 85 percent range (Claes & others, 2010).

**Sexual Attitudes and Behavior** Although the ability of men and women to function sexually shows little biological decline in middle adulthood, sexual activity usually occurs less frequently in midlife than in early adulthood (Fileborn & others, 2017; Rees & others, 2018). Figure 3 shows the age trends in frequency of sex from the Sex in America survey. The frequency of having sex was greatest for individuals aged 25 to 29 years old (47 percent had sex twice a week or more) and dropped off for individuals in their fifties (23 percent of 50- to 59-year-old males said they had sex twice a week or more, and only 14 percent of the females in this age group reported this frequency) (Michael & others, 1994). Note, though, that the Sex in America survey may underestimate the frequency of sexual activity of middle-aged adults because the data were collected prior to the widespread use of erectile dysfunction drugs such as Viagra. Other research indicates that middle-aged men want sex more, think about it more, and masturbate more often than middle-aged women (Stones & Stones, 2007). For many other forms of sexual behavior, such as kissing and hugging, sexual touching, and oral sex, male and female middle-aged adults report similar frequency of engagement (Stones & Stones, 2007).

If middle-aged adults have sex less frequently than they did in early adulthood, does it mean they are less satisfied with their sex life? In a Canadian study of 40- to 64-year-olds, only

POINTS IN ADULT DEVELOPMENT.** Why  
do you think the frequency of sex declines as  
men and women get older?

30 percent reported that their sexual life was less satisfying than it had been when they were in their twenties (Wright, 2006). In a recent study, middle-aged and older adults who had sex more frequently also had better overall cognitive functioning, especially working memory and executive function (Wright, Jenks, & Demeyere, 2018).

Living with a spouse or partner makes all the difference in whether people engage in sexual activity, especially for women over 40 years of age. In one study conducted as part of the Midlife in the United States Study (MIDUS), 95 percent of women in their forties with partners said that they had been sexually active in the

last six months, compared with only 53 percent of those without partners (Brim, 1999). By their fifties, 88 percent of women living with a partner have been sexually active in the last six months, but only 37 percent of those who are neither married nor living with someone say they have had sex in the last six months.

A large-scale study of U.S. adults 40 to 80 years of age found that premature ejaculation (26 percent) and erectile difficulties (22 percent) were the most common sexual problems of older men, while lack of sexual interest (33 percent) and lubrication difficulties (21 percent) were the most common sexual problems of older women (Laumann & others, 2009).

A person's health in middle age is a key factor in sexual activity (Almont & others, 2017; Rees & others, 2018). For example, a study of aging adults 55 years and older revealed that their level of sexual activity was associated with their physical and mental health (Bach & others, 2013).

## Review Connect Reflect

**LG2** Discuss physical changes in middle adulthood.

### Review

- What are some key physical changes in middle adulthood?
- How would you characterize health and disease in middle adulthood?
- What are the main causes of death in middle age?
- What are the sexual lives of middle-aged adults like?

### Connect

- In this section, you read that the production of estrogen by the ovaries

declines dramatically in menopause. What have you learned about estrogen's role in puberty?

### Reflect Your Own Personal Journey of Life

- If you are a young or middle-aged adult, what can you do at this point in your life to optimize your health in middle age? If you are an older adult, what could you have done differently to optimize your health in middle age?

## 3 Cognitive Development

**LG3**

Identify cognitive changes in middle adulthood.

Intelligence

Information Processing

We have seen that middle-aged adults may not see as well, run as fast, or be as healthy as they were in their twenties and thirties. But what about their cognitive skills? Do these skills decline as we enter and move through middle adulthood? To answer this question, we will explore the possibility of age-related cognitive changes in intelligence and information processing.

## INTELLIGENCE

Our exploration of possible changes in intelligence in middle adulthood focuses on the concepts of fluid and crystallized intelligence, the Seattle Longitudinal Study, and cohort effects.

**Fluid and Crystallized Intelligence** John Horn argues that some abilities begin to decline in middle age while others increase (Horn & Donaldson, 1980). Horn maintains that **crystallized intelligence**, an individual's accumulated information and verbal skills, continues to increase in middle adulthood, whereas **fluid intelligence**, one's ability to reason abstractly, begins to decline in middle adulthood (see Figure 4).

Horn's data were collected in a cross-sectional manner. Remember that a cross-sectional study assesses individuals of different ages at the same point in time. For example, a cross-sectional study might assess the intelligence of different groups of 40-, 50-, and 60-year-olds in a single evaluation, such as in 1980. The 40-year-olds in the study would have been born in 1940 and the 60-year-olds in 1920—different eras that offered different economic and educational opportunities. The 60-year-olds likely had fewer educational opportunities as they grew up. Thus, if we find differences between 40- and 60-year-olds on intelligence tests when they are assessed cross-sectionally, these differences might be due to cohort effects related to educational differences rather than to age.

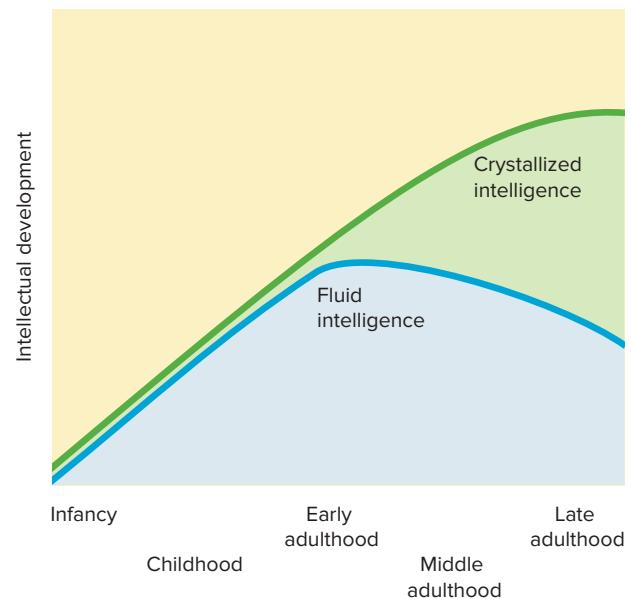

By contrast, in a longitudinal study, the same individuals are studied over a period of time. Thus, a longitudinal study of intelligence in middle adulthood might consist of giving the same intelligence test to the same individuals when they are 40, 50, and 60 years of age. As we see next, whether data on intelligence are collected cross-sectionally or longitudinally can make a difference in what is found about changes in crystallized and fluid intelligence and about intellectual decline (Abrams, 2009; Schaie, 2011a, b, 2013).

**The Seattle Longitudinal Study** The Seattle Longitudinal Study that involves extensive evaluation of intellectual abilities during adulthood was initiated by K. Warner Schaie (1994, 1996, 2005, 2010, 2011a, b, 2013). Participants have been assessed at seven-year intervals since 1956: 1963, 1970, 1977, 1984, 1991, 1998, 2005, and 2012. Five hundred individuals initially were tested in 1956. New waves of participants are added periodically. The main focus in the Seattle Longitudinal Study has been on individual change and stability in intelligence, and the study is regarded as one of the most thorough examinations of how people develop and change as they go through adulthood.

The main mental abilities tested in this study are:

- *Verbal comprehension* (ability to understand ideas expressed in words)
- *Verbal memory* (ability to encode and recall meaningful language units, such as a list of words)
- *Numeric facility* (ability to perform simple mathematical computations such as addition, subtraction, and multiplication)
- *Spatial orientation* (ability to visualize and mentally rotate stimuli in two- and three-dimensional space)
- *Inductive reasoning* (ability to recognize and understand patterns and relationships in a problem and to use this understanding to solve other instances of the problem)
- *Perceptual speed* (ability to quickly and accurately make simple discriminations in visual stimuli)

As shown in Figure 5, the highest level of functioning for four of the six intellectual abilities occurred in middle adulthood (Schaie, 2013). For both women and men, peak performance on verbal ability, verbal memory, inductive reasoning, and spatial orientation was attained in middle age. For only two of the six abilities—numeric facility and perceptual speed—were there declines during middle age. Perceptual speed showed the earliest decline, actually beginning

**FIGURE 4**

### FLUID AND CRYSTALLIZED INTELLECTUAL

**DEVELOPMENT ACROSS THE LIFE SPAN.** According to Horn, crystallized intelligence (based on cumulative learning experiences) increases throughout the life span, but fluid intelligence (the ability to perceive and manipulate information) steadily declines from middle adulthood onward.

#### developmental connection

##### Cognitive Theory

A fifth, postformal stage of cognitive development has been proposed to describe cognitive advances in early adulthood. Connect to “Physical and Cognitive Development in Early Adulthood.”

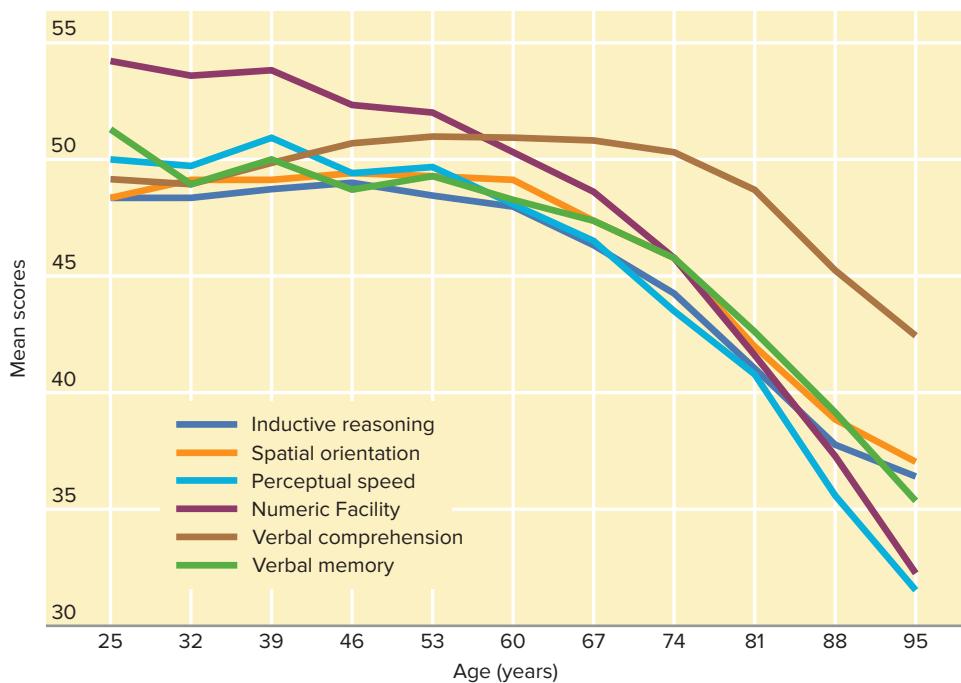

#### developmental connection

##### Memory

Some types of memory decline more than others in older adults. Connect to “Cognitive Development in Late Adulthood.”

**crystallized intelligence** Accumulated information and verbal skills, which increase in middle adulthood, according to Horn.

**fluid intelligence** The ability to reason abstractly, which begins to decline from middle adulthood onward, according to Horn.

**FIGURE 5**  
**LONGITUDINAL CHANGES IN SIX INTELLECTUAL ABILITIES FROM AGE 25 TO AGE 95**

Source: K. W. Schaie: "Longitudinal Changes in Six Intellectual Abilities from Age 25 to Age 95" Figure 5.7a, in *Developmental Influences on Intelligence: The Seattle Longitudinal Study* (2nd ed.), 2013, p. 162.

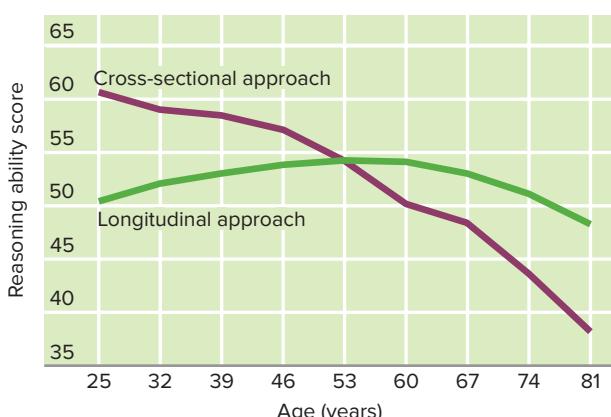

in many intellectual skills. Some researchers have found that cross-sectional studies indicate more than 90 percent of cognitive decline in aging is due to a slowing of processing speed, whereas longitudinal studies reveal that 20 percent or less of cognitive decline is due to slowing of processing speed (MacDonald & others, 2003; MacDonald & Stawski, 2015, 2016; Stawski, Sliwinski, & Hofer, 2013).

In further analysis, Schaie (2007) examined generational differences in parents and their children over a seven-year time frame from 60 to 67 years of age. That is, parents were assessed when they were 60 to 67 years of age; and when their children reached 60 to 67 years of age, they also were assessed. Higher levels of cognitive functioning occurred for the second generation in inductive reasoning, verbal memory, and spatial orientation, whereas the first generation scored higher on numeric ability. Noteworthy was the finding that the parent generation showed cognitive decline from 60 to 67 years of age, but their offspring showed stability or modest increases in cognitive functioning across the same age range.

Such differences across generations involve cohort effects. In one analysis, Schaie (2011b) concluded that the advances in cognitive functioning in middle age that have occurred in recent decades are likely due to factors such as educational attainment, occupational structures (increasing numbers of workers in professional occupations and work complexity), health care and lifestyles, immigration, and social interventions in poverty. The impressive gains in cognitive functioning in recent cohorts have been documented more clearly for fluid intelligence than for crystallized intelligence (Schaie, 2011b).

The results from Schaie's study that have been described so far focus on average cognitive stability or change for all participants across the middle adulthood years. Schaie and Sherry Willis (Schaie, 2005; Willis & Schaie, 2005) examined individual differences for the participants in the Seattle study and found substantial individual variations. They classified participants as "decliners," "stable," or "gainers" for three categories—numeric ability, delayed recall (a verbal memory task), and word fluency—from 46 to 60 years of age. The largest percentage of decline (31 percent) or gain (16 percent) occurred for delayed recall; the largest percentage of stable scores (79 percent) occurred for numeric ability. Word fluency declined in 20 percent of the individuals from 46 to 60 years of age.

Might the individual variations in cognitive trajectories in midlife be linked to cognitive impairment in late adulthood? In Willis and Schaie's

**FIGURE 6**  
**CROSS-SECTIONAL AND LONGITUDINAL COMPARISONS OF INTELLECTUAL CHANGE IN MIDDLE ADULTHOOD. Why do you think reasoning ability peaks during middle adulthood?**

in early adulthood. Interestingly, in terms of John Horn's ideas that were discussed earlier, for the participants in the Seattle Longitudinal Study, middle age was a time of peak performance for some aspects of both crystallized intelligence (verbal ability) and fluid intelligence (spatial orientation and inductive reasoning).

When Schaie (1994) assessed intellectual abilities both cross-sectionally and longitudinally, he found declines to be more likely in the cross-sectional than in the longitudinal assessments. For example, as shown in Figure 6, when assessed cross-sectionally, inductive reasoning showed a consistent decline during middle adulthood. In contrast, when assessed longitudinally, inductive reasoning increased until toward the end of middle adulthood when it began to show a slight decline. In Schaie's (2008, 2009, 2010, 2011a, b, 2013, 2016) view, it is in middle adulthood, not early adulthood, that people reach a peak

analysis, cognitively normal and impaired older adults did not differ on measures of vocabulary, spatial orientation, and numeric ability in middle adulthood. However, declines in memory (immediate recall and delayed recall), word fluency, and perceptual speed in middle adulthood were linked to neuropsychologists' ratings of the individuals' cognitive impairment in late adulthood.

Some researchers disagree with Schaie that middle adulthood is the time when the level of functioning in a number of cognitive domains is maintained or even increases (Finch, 2009). For example, Timothy Salthouse (2009, 2012, 2014, 2016, 2017, 2018) recently has argued that cross-sectional research on aging and cognitive functioning should not be dismissed and that this research indicates reasoning, memory, spatial visualization, and processing speed begin declining in early adulthood and show further decline in the fifties. Salthouse (2009, 2012) agrees that cognitive functioning involving accumulated knowledge, such as vocabulary and general information, does not show early age-related decline but rather continues to increase at least until 60 years of age. Salthouse (2014, 2016) recently has argued that a main reason for different trends in longitudinal and cross-section comparisons of cognitive functioning is that prior experience with tests increases scores the next time a test is taken.

Salthouse (2009, 2012, 2018) has emphasized that a lower level of cognitive functioning in early and middle adulthood is likely due to age-related neurobiological decline. Cross-sectional studies have shown that the following neurobiological factors decline during the twenties and thirties, then continue to decline in middle adulthood: regional brain volume, cortical thickness, synaptic density, some aspects of myelination, the functioning of some aspects of neurotransmitters such as dopamine and serotonin, blood flow in the cerebral cortex, and the accumulation of tangles in neurons (Del Tredici & Braak, 2008; Finch, 2009; Hsu & others, 2008; Pieperhoff & others, 2008).

Schaie (2009, 2010, 2011a, b, 2013) continues to emphasize that longitudinal studies hold the key to determining age-related changes in cognitive functioning and that middle age is the time when many cognitive skills actually peak. In the next decade, expanding research on age-related neurobiological changes and their possible links to cognitive skills should further refine our knowledge about age-related cognitive functioning in the adult years (Lustig & Lin, 2016; Park & Festini, 2018; Wig & others, 2017).

## INFORMATION PROCESSING

As we saw in our discussion of theories of cognitive development from infancy through adolescence, the information-processing approach provides another way to examine cognitive abilities (Braithwaite & Siegler, 2018; Braithwaite, Tian, & Siegler, 2018; Siegler, 2017; Siegler & Braithwaite, 2017). Among the information-processing changes that take place in middle adulthood are those involved in speed of processing information, memory, expertise, and practical problem-solving skills.

**Speed of Information Processing** As we saw in Schaie's (1994, 1996, 2011a, b, 2013) Seattle Longitudinal Study, perceptual speed begins declining in early adulthood and continues to decline in middle adulthood. A common way to assess speed of information processing is through a reaction-time task, in which individuals simply press a button as soon as they see a light appear. Middle-aged adults are slower to push the button when the light appears than young adults are. However, keep in mind that the decline is not dramatic—under 1 second in most investigations.

A current interest focuses on possible causes for the decline in speed of processing information in adults (Salthouse, 2009, 2012, 2018). The causes may occur at different levels of analysis, such as cognitive ("maintaining goals, switching between tasks, or preserving internal representations despite distraction"), neuroanatomical ("changes in specific brain regions, such as the prefrontal cortex"), and neurochemical ("changes in neurotransmitter systems" such as dopamine) (Hartley, 2006, p. 201).

**Memory** In Schaie's (1994, 1996, 2013) Seattle Longitudinal Study, verbal memory peaked during the fifties. However, in some other studies verbal memory has shown a decline

K. Warner Schaie (*right*) is one of the leading pioneers in the field of life-span development. He is shown here with two older adults who are actively using their cognitive skills. Schaie's research represents one of the most thorough examinations of how individuals develop and change as they go through the adult years.

### Memory

Working memory plays an important role in many aspects of children's cognitive and language development. Connect to "Physical and Cognitive Development in Middle and Late Childhood."

in middle age, especially when assessed in cross-sectional studies (Salthouse, 2009, 2012, 2018). For example, when people were asked to remember lists of words, numbers, or meaningful prose, younger adults outperformed middle-aged adults (Salthouse & Skovronek, 1992). Although there still is some controversy about whether memory declines during middle adulthood, most experts conclude that it does decline at some point during this period of adult development (Davis & others, 2017; Ferreira & others, 2015; Lundervold, Wollschlager, & Wehling, 2014; Salthouse, 2017, 2018). However, some experts argue that studies that have concluded there is a decline in memory during middle age often have compared young adults in their twenties with older middle-aged adults in their late fifties and even have included some individuals in their sixties (Schaie, 2000). In this view, memory decline is either nonexistent or minimal in the early part of middle age but does occur in the latter part of middle age or in late adulthood.

Cognitive aging expert Denise Park (2001) argues that starting in late middle age, more time is needed to learn new information. The slowdown in learning new information has been linked to changes in *working memory*, the mental "workbench" where individuals manipulate and assemble information when making decisions, solving problems, and comprehending written and spoken language (Baddeley, 2007, 2012, 2013, 2015, 2017, 2018a, b). In this view, in late middle age working memory capacity becomes more limited. Think of this situation as an overcrowded desk with many items in disarray. As a result of the overcrowding and disarray, long-term memory becomes less reliable, more time is needed to enter new information into long-term storage, and more time is required to retrieve the information. Thus, Park concludes that much of the blame for declining memory in late middle age is a result of information overload that builds up as we go through the adult years.

Memory decline is more likely to occur when individuals don't use effective memory strategies, such as organization and imagery (Small & others, 2012). By organizing lists of phone numbers into different categories, or imagining the phone numbers as representing different objects around the house, many individuals can improve their memory in middle adulthood.

## developmental connection

### Information Processing

One study found that 10- and 11-year-old children who were experienced chess players ("experts") remembered more about chess pieces than college students who were not chess players ("novices"). Connect to "Physical and Cognitive Development in Middle and Late Childhood."

**Expertise** Because it takes so long to attain, expertise often shows up more in middle adulthood than in early adulthood (Charness & Krampe, 2008). Recall that expertise involves having extensive, highly organized knowledge and understanding of a particular domain. Developing expertise and becoming an "expert" in a field usually is the result of many years of experience, learning, and effort (Ericsson, 2017; Ericsson & others, 2018).

Strategies that distinguish experts from novices include these:

- Experts are more likely to rely on their accumulated experience to solve problems.
- Experts often process information automatically and analyze it more efficiently when solving a problem in their domain than novices do.
- Experts have better strategies and shortcuts for solving problems in their domain than novices do.
- Experts are more creative and flexible in solving problems in their domain than novices are.

**Practical Problem Solving** Everyday problem solving is another important aspect of cognition (Cheek, Piercy, & Kohlenberg, 2015; Kimbler, 2013). Nancy Denney (1986, 1990) observed circumstances such as how young and middle-aged adults handled a landlord who would not fix their stove and what they did if a bank failed to deposit a check. She found that the ability to solve such practical problems improved through the forties and fifties as individuals accumulated practical experience.

However, since Denney's research other studies have been conducted on everyday problem-solving and decision-making effectiveness across the adult years (Cheek, Piercy, & Kohlenberg, 2015; Margrett & Deshpande-Kamat, 2009). In a recent study of individuals from 24 to 93 years of age, everyday problem solving showed an increase in performance from early adulthood to middle adulthood, with performance then beginning to decrease at about 50 years of age (Chen, Hertzog, & Park, 2017). Also in this study, fluid intelligence predicted performance on everyday problem solving in young adults but with increasing age, crystallized intelligence became a better predictor.

## Review Connect Reflect

**LG3** Identify cognitive changes in middle adulthood.

### Review

- How does intelligence develop in middle adulthood?
- What changes take place in processing information during middle age?

### Connect

- In this section you read about longitudinal and cross-sectional studies of intelligence. What are the pros and cons of these two research approaches?

### Reflect Your Own Personal Journey of Life

- Think about your life and the lives of your parents and grandparents. Are

there experiences that you are likely to have, are having, or have had that will enhance your intelligence in middle age more than the experiences they had or are having? Also, think about experiences that you are likely to have or have had in the past that might not be as intelligence-enhancing as those experiences of your parents or grandparents. For example, have we become too dependent on calculators, computers, and the Internet for our knowledge and information?

## 4 Careers, Work, and Leisure

**LG4**

Characterize career development, work, and leisure in middle adulthood.

Work in Midlife

Career Challenges and Changes

Leisure

What are some issues that workers face in midlife? What role does leisure play in the lives of middle-aged adults?

### WORK IN MIDLIFE

The role of work, whether one works in a full-time career, in a part-time job, as a volunteer, or as a homemaker, is central during middle adulthood (Cahill, Giandrea, & Quinn, 2016; Wang & Shi, 2016). Many middle-aged adults reach their peak in position and earnings. However, they may also be saddled with multiple financial burdens including rent or mortgage, child care, medical bills, home repairs, college tuition, loans to family members, or bills from nursing homes.

In 2015 in the United States, 79.4 percent of 45- to 54-year-olds were in the workforce (a decrease of 3.4 percent since 2000) and 64.1 percent of 55- to 64-year-olds were in the workforce (an increase of 8 percent since 2000) (Short, 2015a, b). Later in the text, we will describe various aspects of workforce participation of individuals 65 and over in the United States, which has increased a remarkable 50 percent since 2000 (Short, 2015b).

Do middle-aged workers perform their work as competently as younger adults? Age-related declines occur in some occupations, such as air traffic controllers and professional athletes, but for most jobs, no differences have been found in the work performance of young adults and middle-aged adults (Salthouse, 2012; Sturman, 2003).

However, leading Finnish researcher Clas-Hakan Nygard (2013) concludes from his longitudinal research that the ability to work effectively peaks during middle age because of increased motivation, work experience, employer loyalty, and better strategic thinking. Nygard also has found that the quality of work done by employees in middle age is linked to how much their work is appreciated and how well they get along with their immediate supervisors. And Nygard and his colleagues discovered that work ability in middle age was linked to mortality and disability 28 years later (von Bonsdorff & others, 2011, 2012).

For many people, midlife is a time of evaluation, assessment, and reflection in terms of the work they are doing now and what they want to do in the future (Cahill, Giandrea, & Quinn, 2015). Among the work issues that some people face in midlife are recognizing limitations in career progress, deciding whether to change jobs or careers, determining how and when to rebalance family and work, and planning for retirement (Sterns & Huyck, 2001).

### developmental connection

#### Work

Work defines people in fundamental ways, influencing their financial standing, housing, the way they spend their time, where they live, their friendships, and their health. Connect to “Physical and Cognitive Development in Early Adulthood.”

What characterizes work in middle adulthood?  
©Ariel Skelly/Getty Images

Couples increasingly have both spouses in the workforce who are expecting to retire. Historically retirement has been a male transition, but today far more couples are planning two retirements—his and hers (Moen, 2009b; Moen, Kelly, & Magennis, 2008).

Economic downturns and recessions in the United States have forced some middle-aged individuals into premature retirement because of job loss and fear of not being able to reenter the work force (Cahill, Giandrea, & Quinn, 2016). Such premature retirement also may result in accumulating insufficient financial resources to cover an increasingly long retirement period (de Wind & others, 2014).

## CAREER CHALLENGES AND CHANGES

Middle-aged workers face several important challenges in the twenty-first century (Brand, 2014). These include the globalization of work, rapid developments in information technologies, downsizing of organizations, early retirement, and concerns about pensions and health care.

Globalization has replaced what was once a primarily White male workforce with employees of different ethnic and national backgrounds (Cahill, Giandrea, & Quinn, 2016; Short, 2015a). To improve profits, many companies are restructuring, downsizing, and outsourcing jobs. One of the outcomes of these changes is to offer incentives to middle-aged employees to retire early—in their fifties, or in some cases even forties, rather than their sixties.

The decline in defined-benefit pensions and increased uncertainty about the fate of health insurance are decreasing the sense of personal control among middle-aged workers. As a consequence, many are delaying retirement.

Some midlife career changes are self-motivated; others are the consequence of losing one's job (Brand, 2014). Some individuals in middle age decide that they don't want to spend the rest of their lives doing the same kind of work they have been doing (Hoyer & Roodin, 2009). One aspect of middle adulthood involves adjusting idealistic hopes to accommodate realistic possibilities in light of how much time individuals have before they retire and how fast they are reaching their occupational goals (Levinson, 1978). If individuals perceive that they are behind schedule, if their goals are unrealistic, they don't like the work they are doing, or their job has become too stressful, they could become motivated to change jobs.

A final point to make about career development in middle adulthood is that cognitive factors earlier in development are linked to occupational attainment in middle age. In one study, task persistence at 13 years of age was related to occupational success in middle age (Andersson & Bergman, 2011).

Sigmund Freud once commented that the two things adults need to do well to adapt to society's demands are to work and to love. To his list we add "to play." In our fast-paced society, it is all too easy to get caught up in the frenzied, hectic pace of our achievement-oriented work world and ignore leisure and play. Imagine your life as a middle-aged adult. *What would be the ideal mix of work and leisure? What leisure activities do you want to enjoy as a middle-aged adult?*

©Digital Vision/Getty Images

**leisure** The pleasant times after work when individuals are free to pursue activities and interests of their own choosing.

## LEISURE

As adults, not only must we learn how to work well, but we also need to learn how to relax and enjoy leisure (Finkel, Andel, & Pedersen, 2018). **Leisure** refers to the pleasant times after work when individuals are free to pursue activities and interests of their own choosing—hobbies, sports, or reading, for example. In one analysis of research on what U.S. adults regret the most, not engaging in more leisure was one of the top six regrets (Roese & Summerville, 2005).

Leisure can be an especially important aspect of middle adulthood (Nicolaisen, Thorsen, & Eriksen, 2012). By middle adulthood, more money is available to many individuals, and there may be more free time and paid vacations. In short, midlife changes may produce expanded opportunities for leisure.

In one study, 12,338 men 35 to 57 years of age were assessed each year for five years regarding whether or not they took vacations (Gump & Matthews, 2000). Then the researchers examined the medical and death records over nine years for men who lived for at least a year after the last vacation survey. Compared with those who never took vacations, men who went on annual vacations were 21 percent less likely to die over the nine years and 32 percent less likely to die of coronary heart disease. And a Finnish study found that engaging in little leisure-time activity in middle age was linked to risk of cognitive impairment in late adulthood (23 years later) (Virta & others, 2013).

Adults at midlife need to begin preparing psychologically for retirement. Constructive and fulfilling leisure activities in middle adulthood are an important part of this preparation. If an adult develops leisure activities that can be continued into retirement, the transition from work to retirement can be less stressful.

Also, the type of leisure activity may be linked to different outcomes (Hagnas & others, 2018). A recent study found that engaging in higher complexity of work before retirement was associated with a smaller decline in cognitive performance in retirement (Andel, Finkel, & Pedersen, 2016). However, when those who had worked in occupations with fewer cognitive challenges prior to retirement engaged in physical (sports, walking) and cognitive (reading books, doing puzzles, and playing chess) leisure activities during retirement, they showed less cognitive decline. Also, a Danish longitudinal study of 20- to 93-year-olds found that those who engaged in a light level of leisure-time physical activity lived 2.8 years longer, those who engaged in a moderate level of leisure-time physical activity lived 4.5 years longer, and those who engaged in high level of leisure-time physical activity lived 5.5 years longer (Schnohr & others, 2017).

Further, a study revealed that when middle-aged adults engaged in active leisure pursuits they had a higher level of cognitive performance in late adulthood (Ihle & others, 2015). And in another recent study, individuals who engaged in a greater amount of sedentary screen-based leisure-time activity (TV, video games, computer use) had shorter telomere length (telomeres cover the end of chromosomes, and as people age their telomeres become shorter and this shorter telomere length is linked to mortality) (Loprinzi, 2015b).

Research also has highlighted links between stress and leisure time (Qian, Yamal, & Almeida, 2014a, b, c). In one study, after individuals experienced daily stressful events, if they engaged in more leisure time than usual on those days, the leisure time served as a positive coping strategy in improving their moods.

## Review Connect Reflect

## 5 Religion, Spirituality, and Meaning in Life

Religion, Spirituality, and Adult Lives

LG5

Explain the roles of religion, spirituality, and meaning in life during middle adulthood.

Religion, Spirituality, and Health

Meaning in Life

What roles do religion and spirituality play in our development as adults? Is the meaning of life an important theme for many middle-aged adults?

## RELIGION, SPIRITUALITY, AND ADULT LIVES

Can religion be distinguished from spirituality? Pamela King and her colleagues (2011) provide the following distinctions:

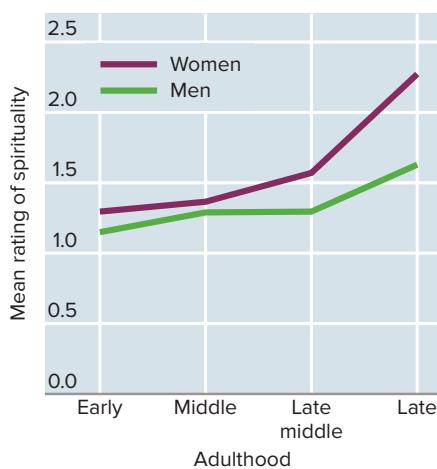

- **Religion** is an organized set of beliefs, practices, rituals, and symbols that increases an individual's connection to a sacred or transcendent other (God, higher power, or ultimate truth).
- **Religiousness** refers to the degree of affiliation with an organized religion, participation in its prescribed rituals and practices, connection with its beliefs, and involvement in a community of believers.

**religion** An organized set of beliefs, practices, rituals, and symbols that increases an individual's connection to a sacred or transcendent other (God, higher power, or higher truth).

**religiousness** The degree to which an individual is affiliated with an organized religion, participates in prescribed rituals and practices, feels a sense of connection with its beliefs, and is involved in a community of believers.

What roles do religion and spirituality play in the lives of middle-aged adults?  
©Erik S. Lesser/Newscom

**FIGURE 7**  
**LEVEL OF SPIRITUALITY IN FOUR ADULT AGE PERIODS.**

**AGE PERIODS.** In a longitudinal study, the spirituality of individuals in four different adult age periods—early (thirties), middle (forties), late middle (mid-fifties/early sixties), and late (late sixties/early seventies) adulthood—was assessed (Wink & Dillon, 2002). Based on responses to open-ended questions in interviews, the spirituality of the individuals was coded on a 5-point scale with 5 being the highest level of spirituality and 1 the lowest.

**spirituality** Experiencing something beyond oneself in a transcendent manner and living in a way that benefits others and society.

- **Spirituality** involves experiencing something beyond oneself in a transcendent manner and living in a way that benefits others and society.

In thinking about religion, spirituality, and adult development, it is important to consider the role of individual differences. Religion and spirituality are powerful influences for some adults but hold little or no significance for others (Krause & Hayward, 2016; McCullough & others, 2005). In a recent national poll, 92 percent of U.S. adults said that they believe in God and 50 percent reported that religion is very important to them (Pew Research Center, 2015). Further, the influence of religion and spirituality in people's lives may change as they develop (Sapp, 2010). In John Clausen's (1993) longitudinal investigation, some individuals who had been strongly religious in their early adult years became less so in middle age, while others became more religious in middle age.

In the MacArthur Foundation Study of Midlife Development, more than 70 percent of U.S. middle-aged adults described themselves as religious and said that spirituality was a major part of their lives (Brim, 1999). In a longitudinal study of individuals from their early thirties through their early seventies, a significant increase in spirituality occurred between late middle adulthood (mid-fifties/early sixties) and late adulthood (Wink & Dillon, 2002) (see Figure 7). Another survey found that 77 percent of 30- to 49-year-olds and 84 percent of 50- to 64-year-olds reported having a religious affiliation, compared with 67 percent of 18- to 29-year-olds and 90 percent of adults age 90 and over (Pew Research Center, 2012).

Women have consistently shown a stronger interest in religion and spirituality than men have. In the longitudinal study just described, the spirituality of women increased more than that of men in the second half of life (Wink & Dillon, 2002). And in a recent national U.S. study, 60 percent of women compared with 47 percent of men said that religion is very important in their lives (Pew Research Center, 2016).

## RELIGION, SPIRITUALITY, AND HEALTH

How might religion influence physical health? Some cults and religious sects encourage behaviors that can be damaging to health, such as ignoring sound medical advice (Manca, 2013; Williams & Sternthal, 2007). For individuals in the religious mainstream, researchers increasingly are finding that spirituality/religion is positively linked to health (Dilmaghani, 2018; Krause & Hayward, 2016; Park & Ono, 2018). In a recent study, spiritual well-being predicted which heart failure patients would still be alive five years later (Park & others, 2016). In another study, adults who volunteered had lower resting pulse rates and their resting pulse rates improved if they were more deeply committed to religion (Krause, Ironson, & Hill, 2017). And in one study of middle-aged adults, those who attended church had a lower level of allostatic load (a wearing down of one's body because of constant stress) than their counterparts who did not attend church (Bruce & others, 2017). In an analysis of a number of studies, adults with a higher level of spirituality/religion had an 18 percent reduction in mortality (Lucchetti, Lucchetti, & Koenig, 2011). In this analysis, a high level of spirituality/religion had a stronger link to longevity than 60 percent of 25 other health interventions (such as eating fruits and vegetables and taking statin drugs for cardiovascular disease). In *Connecting Development to Life*, we explore links between religion, spirituality, and coping.

In sum, various dimensions of religion and coping can help some individuals cope more effectively with challenges in their lives (Holt & others, 2017; Krause & Hayward, 2016; Park, 2013). Religious counselors often advise people about mental health and coping. To read about the work of one religious counselor, see *Connecting with Careers*.

## MEANING IN LIFE

Austrian psychiatrist Viktor Frankl's mother, father, brother, and wife died in the concentration camps and gas chambers in Auschwitz, Poland. Frankl survived the concentration camp and went on to write about meaning in life. In his book *Man's Search for Meaning*, Frankl (1984) emphasized each person's uniqueness and the finiteness of life. He argued that examining the finiteness of our existence and the certainty of death adds meaning to life. If life

# connecting development to life

## Religion, Spirituality, and Coping

What is the connection between religion, spirituality, and the ability to cope with stress? Researchers are increasingly finding that religion and spirituality are related to well-being (Holt & others, 2017; Krause & Hayward, 2016). One study revealed that highly religious individuals were less likely than their moderately religious, somewhat religious, and non-religious counterparts to be psychologically distressed (Park, 2013). Also, in a study of 850 medically ill patients admitted to an acute-care hospital, religious coping was related to low rates of depression (Koenig & others, 1992).

Religious coping is often beneficial during times of high stress (Pargament & others, 2013; Park & others, 2017). For example, in one study individuals were divided into those who were experiencing high stress and those with low stress (Manton, 1989). In the high-stress group, spiritual support was significantly related to low rates of depression and high levels of self-esteem. No such links were found in the low-stress group. One study revealed that when religion was an important aspect of people's lives, they frequently prayed, had positive religious core beliefs, worried less, were less anxious, and had a lower level of depressive symptoms (Rosmarin, Krumrei, & Andersson, 2009). And in a recent study, among veterans with combat exposure, negative religious coping was associated with higher posttraumatic stress disorder

(PTSD) symptoms, while positive religious/spiritual coping was linked to higher perceived posttraumatic growth (PPTG) symptoms (Park & others, 2017).

A recent interest in linking religion and coping focuses on **meaning-making coping**, which involves drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of chronic stress such as when a loved one dies (Ahmadi & others, 2017; Sloan & others, 2017). In Crystal Park's (2007, 2013) view, religious individuals experience more disruption of their beliefs, values, and goals immediately after the death of a loved one than individuals who are not religious. Eventually, though, individuals who are religious often show better adjustment to the loss. Initially, religion is linked with more depressed feelings about a loved one's death. Over time, however, as religious individuals search for meaning in their loss, the depressed feelings lessen. Thus, religion can serve as a meaning system through which bereaved individuals are able to reframe their loss and even find avenues of personal growth.

How is religion linked to the ability to cope with stress?

©Image Source/Alamy

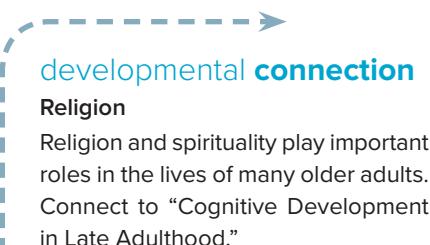

If religion is linked to the ability to cope with stress better and if stress is linked to disease (as indicated earlier in the chapter), what can be concluded about a possible indirect link between religion and disease?

were not finite, said Frankl, we could spend our life doing just about anything we pleased because time would continue forever.

Frankl said that the three most distinct human qualities are spirituality, freedom, and responsibility. Spirituality, in his view, does not have a religious underpinning. Rather, it refers to a human being's uniqueness of spirit, philosophy, and mind. Frankl proposed that people need to ask themselves questions such as why they exist, what they want from life, and what the meaning of their life might be.

It is in middle adulthood that individuals begin to be faced with death more often, especially the deaths of parents and other older relatives. Also, when facing less time ahead of them than behind them, many individuals in middle age begin to ask and evaluate the questions that Frankl proposed (Cohen, 2009). And, as indicated in *Connecting Development to Life*, meaning-making coping is especially helpful in times of chronic stress and loss.

Having a sense of meaning in life can lead to clearer guidelines for living one's life and enhanced motivation to take care of oneself and reach goals (Ju, 2017; Zhang, 2018). A higher level of meaning in life also is linked to a higher level of psychological well-being and physical health (Park, 2012). Roy Baumeister and Kathleen Vohs (2002, pp. 610–611) argue that this

**meaning-making coping** Involves drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of chronic stress such as when a loved one dies.

## Gabriel Dy-Liacco, University Professor and Pastoral Counselor

Gabriel Dy-Liacco currently is a professor in religious and pastoral counseling at Regent University in Virginia Beach, Virginia. He obtained his Ph.D. in pastoral counseling from Loyola College in Maryland and has worked as a psychotherapist in mental health settings such as a substance-abuse program, military family center, psychiatric clinic, and community mental health center. Earlier in his career he was a pastoral counselor at the Pastoral Counseling and Consultation Centers of Greater Washington, D.C., and taught at Loyola University in Maryland. As a pastoral counselor, he works with adolescents and adults in the aspects of their lives that they show the most concern about—psychological, spiritual, or the interface of both. Having lived in Peru, Japan, and the Philippines, he brings considerable multicultural experience to teaching and counseling settings.

Gabriel Dy-Liacco, university professor and pastoral counselor.

What characterizes the search for meaning in life?

©Eric Audras/Getty Images

When more time stretches behind than stretches before one, some assessments, however reluctantly and incompletely, begin to be made.

—JAMES BALDWIN

American Novelist, 20th Century

quest can be understood in terms of four main needs for meaning that guide how people try to make sense of their lives:

- *Need for purpose.* “Present events draw meaning from their connection with future events.” Purposes can be divided into (1) goals and (2) fulfillments. Life can be oriented toward a future anticipated state, such as living happily ever after or being in love.
- *Need for values.* This “can lend a sense of goodness or positive characterization of life and justify certain courses of action. Values enable people to decide whether certain acts are right or wrong.” Frankl’s (1984) view of meaning in life emphasized values as the main form of meaning that people need.
- *Need for a sense of efficacy.* This involves the “belief that one can make a difference. A life that had purposes and values but no efficacy would be tragic. The person might know what is desirable but could not do anything with that knowledge.” With a sense of efficacy, people believe that they can control their environment, which has positive physical and mental health benefits (Bandura, 2012).
- *Need for self-worth.* Most individuals want to be “good, worthy persons. Self-worth can be pursued individually.”

Researchers are increasingly studying the factors involved in a person’s exploration of meaning in life and whether developing a sense of meaning in life is linked to positive developmental outcomes. Many individuals state that religion played an important role in increasing their exploration of meaning in life (Krause, 2008, 2009; Krause & Hayward, 2016). Studies also suggest that individuals who have found a sense of meaning in life are physically healthier, happier, and less depressed than their counterparts who report that they have not discovered meaning in life (Debats, 1990; Krause, 2004, 2009; Krause & Hayward, 2016).

## Review Connect Reflect

**LG5** Explain the roles of religion, spirituality, and meaning in life during middle adulthood.

# Physical and Cognitive Development in Middle Adulthood

### 1 The Nature of Middle Adulthood

Changing Midlife

Defining Middle Adulthood

**LG1** Explain how midlife is changing, and define middle adulthood.

- As more people live to older ages, the life stage that we think of as middle age seems to be occurring later. A major reason developmentalists are beginning to study middle age is the dramatic increase in the number of individuals entering this period of the life span.
- Middle age involves extensive individual variation. With this variation in mind, we will consider middle adulthood to be entered at about 40 to 45 years of age and exited at approximately 60 to 65 years of age. Middle adulthood is the age period in which gains and losses as well as biological and sociocultural factors balance each other. Some experts conclude that sociocultural factors influence development in midlife more than biological factors do.

## 2 Physical Development

**LG2** Discuss physical changes in middle adulthood.

Physical Changes

Health, Disease, Stress, and Control

Mortality Rates

Sexuality

- The physical changes of midlife are usually gradual. Genetic and lifestyle factors play important roles in whether chronic diseases will appear and when. Among the physical changes of middle adulthood are changes in physical appearance (wrinkles, age spots); height (decrease) and weight (increase); strength, joints, and bones; vision and hearing; cardiovascular system; lungs; and sleep.
- In middle age, the frequency of accidents declines and individuals are less susceptible to colds and allergies. Chronic disorders appear rarely in early adulthood, increase in middle adulthood, and become more common in late adulthood. Arthritis is the leading chronic disorder in middle age, followed by hypertension. Men have more fatal chronic disorders, women more nonfatal ones in middle age. Immune system functioning declines with age.
- Emotional stress likely is an important factor contributing to cardiovascular disease. People who live in a chronically stressed condition are more likely to smoke, overeat, and not exercise. All of these stress-related behaviors are linked with cardiovascular disease. Having a sense of control peaks in middle adulthood and is linked to many aspects of health and disease.
- In middle adulthood, chronic diseases are the main causes of death. Until recently, cardiovascular disease was the leading cause of death in middle age, but now cancer is the leading cause of death in this age group.
- Climacteric is the midlife transition in which fertility declines. The vast majority of women do not have serious physical or psychological problems related to menopause, which usually takes place in the late forties or early fifties, but menopause is an important marker because it signals the end of childbearing capability. Hormone replacement therapy (HRT) augments the declining levels of reproductive hormone production by the ovaries. HRT consists of various forms of estrogen, usually combined with progestin. Recent evidence of risks associated with HRT suggests that its long-term use should be seriously evaluated.
- Men do not experience an inability to father children in middle age, although their testosterone levels decline. A male menopause, like the dramatic decline in estrogen in women, does not occur.
- Sexual activity occurs less frequently in middle adulthood than in early adulthood. Nonetheless, a majority of middle-aged adults show a moderate or strong interest in sex.

## 3 Cognitive Development

**LG3** Identify cognitive changes in middle adulthood.

Intelligence

Information Processing

- Horn argued that crystallized intelligence (accumulated information and verbal skills) continues to increase in middle adulthood, whereas fluid intelligence (ability to reason abstractly) begins to decline. Schaie and Willis found that longitudinal assessments of intellectual abilities are less likely than cross-sectional assessments to find declines in middle adulthood and are more likely to find improvements. The highest level of four intellectual abilities (vocabulary, verbal memory, inductive reasoning, and spatial orientation) occurred in middle age.
- Recent analysis shows considerable individual variation in intellectual abilities across middle adulthood and indicates that variations in some abilities are more predictive of cognitive impairment in late adulthood than others. Salthouse argues that decline in a number of cognitive functions begins in early adulthood and continues through the fifties. Declines have recently been identified in some aspects of neurobiological functioning that may be linked to age-related changes in cognitive functioning.
- Speed of information processing, often assessed through reaction time, continues to decline in middle adulthood. Although Schaie found that verbal memory increased in middle age, some researchers have found that memory declines in middle age. Working memory declines in late middle age. Memory is more likely to decline in middle age when individuals don't use effective strategies.
- Expertise involves having an extensive, highly organized knowledge and an understanding of a particular domain. Expertise often increases in middle adulthood. Practical problem-solving ability remains stable in early and middle adulthood but declines in late adulthood.

## 4 Careers, Work, and Leisure

Work in Midlife

Career Challenges  
and Changes

Leisure

LG4

Characterize career development, work, and leisure in middle adulthood.

- For many people, midlife is a time of reflection, assessment, and evaluation of their current work and what they plan to do in the future. One important issue is whether individuals will continue to do the type of work they currently do or change jobs or careers.
- Today's middle-aged workers face challenges such as the globalization of work, rapid developments in information technologies, downsizing of organizations, pressure to take early retirement, and concerns about pensions and health care. Midlife job or career changes can be self-motivated or forced on individuals.
- We not only need to learn to work well, but we also need to learn to enjoy leisure. Midlife may be an especially important time for leisure because of the physical changes that occur and because of a desire to prepare for an active retirement.

## 5 Religion, Spirituality, and Meaning in Life

Religion, Spirituality,  
and Adult Lives

Religion, Spirituality,  
and Health

Meaning in Life

LG5

Explain the roles of religion, spirituality, and meaning in life during middle adulthood.

- Religion and spirituality are important dimensions of many Americans' lives. Women show a stronger interest in religion and spirituality than men do. It is important to consider individual differences in religious and spiritual interest.
- In some cases, religion and spirituality can be negatively linked to physical health, as when cults or religious sects discourage individuals from obtaining medical care. In mainstream religions, researchers are increasingly finding that religion is positively related to health. Religion and spirituality can enhance coping for some individuals.
- Viktor Frankl argued that examining the finiteness of our existence leads to exploration of meaning in life. Faced with the death of older relatives and less time ahead of them than behind them, many middle-aged individuals increasingly examine life's meaning. Baumeister and Vohs argue that a quest for a meaningful life involves fulfilling four main needs: purpose, values, efficacy, and self-worth.

# SOCIOEMOTIONAL DEVELOPMENT IN MIDDLE ADULTHOOD

## chapter outline

### ① Personality Theories and Adult Development

**Learning Goal 1** Describe personality theories and socioemotional development in middle adulthood

Stages of Adulthood  
The Life-Events Approach  
Stress and Personal Control in Midlife  
Contexts of Midlife Development

### ③ Close Relationships

**Learning Goal 3** Identify some important aspects of close relationships in middle adulthood

Love and Marriage at Midlife  
The Empty Nest and Its Refilling  
Sibling Relationships and Friendships  
Grandparenting  
Intergenerational Relationships

### ② Stability and Change

**Learning Goal 2** Discuss stability and change in development during middle adulthood, as reflected in longitudinal studies

Longitudinal Studies  
Conclusions

©Peter Correzz/The Image Bank/Getty Images

**F**orty-five-year-old Sarah feels tired, depressed, and angry when she looks back on the way her life has gone. She became pregnant when she was 17 and married Ben, the baby's father. They stayed together for three years after their son was born, and then Ben left her for another woman. Sarah went to work as a salesclerk to make ends meet. Eight years later, she married Alan, who had two children from a previous marriage. Sarah stopped working for several years to care for the children. Then, like Ben, Alan started seeing someone else. Sarah found out about it from a friend. Nevertheless, Sarah stayed with Alan for another year. Finally, he was gone so much that she could not take it anymore and decided to divorce him. Sarah went back to work again as a salesclerk; she has been in the same position for 16 years now. During those 16 years, she dated a number of men, but the relationships never seemed to work out. Her son never finished high school and has drug problems. Her father died last year, and Sarah is trying to help her mother financially, although she can barely pay her own bills. Sarah looks in the mirror and does not like what she sees. She sees her past as a shambles, and her future does not look rosy, either.

Forty-five-year-old Wanda feels energetic, happy, and satisfied. As a young woman, she graduated from college and worked for three years as a high school math teacher. She married Andy, who had just finished law school. One year later, they had their first child, Josh. Wanda stayed home with Josh for two years and then returned to her job as a math teacher. Even during her pregnancy, Wanda stayed active and exercised regularly, playing tennis almost every day. After her pregnancy, she kept up her exercise habits. Wanda and Andy had another child, Wendy. Now, as they move into their middle-age years, their children are both off at college, and Wanda and Andy are enjoying spending more time with each other. Last weekend, they visited Josh at his college, and the weekend before they visited Wendy at hers. Wanda continued working as a high school math teacher until six years ago. She had developed computer skills as part of her job and had taken some computer courses at a nearby college. She resigned her math teaching job and took a job with a computer company, where she has already worked her way into management. Wanda looks in the mirror and likes what she sees. She sees her past as enjoyable, although not without hills and valleys, and she looks toward the future with enthusiasm.

## topical connections *looking back* -----

Emerging adulthood, which occurs from approximately 18 to 25 years of age, is a transitional period between adolescence and early adulthood—a time when individuals intensely explore their identity and experience instability in different contexts. A secure attachment style benefits young adults. Love and possibly marriage become central aspects of many young adults' socioemotional development. Searching for a balance between the need for independence and freedom and the need for intimacy and commitment characterizes the lives of many young adults. Many young adults not only are marrying later or not at all but are having children later than in past decades, and many choose to cohabit with a romantic partner.

# preview

As with Sarah and Wanda, there are individual variations in the way people experience middle age. To begin the chapter, we will examine personality theories and development in middle age, including ideas about individual variation. Then we will turn our attention to the ways in which individuals change or stay the same as they go through the adult years. Finally, we will explore a number of aspects of close relationships during middle adulthood.

## 1 Personality Theories and Adult Development

**LG1** Describe personality theories and socioemotional development in middle adulthood.

Stages of Adulthood

The Life-Events Approach

Stress and Personal Control in Midlife

Contexts of Midlife Development

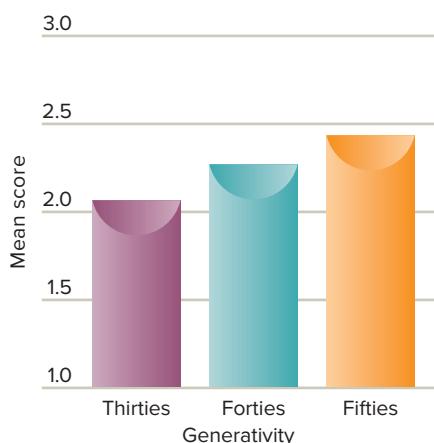

What is the best way to conceptualize middle age? Is it a stage or a crisis? How extensively is middle age influenced by life events? Do middle-aged adults experience stress and personal control differently from adults at other life stages? Is personality linked with contexts such as the point in history when individuals go through midlife, their culture, and their gender?

### STAGES OF ADULTHOOD

The generations of living things pass in a short time, and like runners, hand on the torch of life.

—LUCRETIUS

Roman Poet, 1st Century B.C.

**FIGURE 1**  
**CHANGES IN GENERATIVITY FROM THE THIRTIES THROUGH THE FIFTIES.**

Generativity increased in Smith College women as they aged from their thirties through their fifties (Stewart, Ostrove, & Helson, 2001). The women rated themselves on a 3-point scale indicating the extent to which they thought the statements about generativity were descriptive of their lives. Higher scores reflect greater generativity.

**Erikson's Stage of Generativity Versus Stagnation** Erikson (1968) proposed that middle-aged adults face a significant issue—generativity versus stagnation, which is the name Erikson gave to the seventh stage in his life-span theory. Generativity encompasses adults' desire to leave legacies of themselves to the next generation (Grossman & Gruenewald, 2017; Serrat & others, 2018). Through these legacies adults achieve a kind of immortality. By contrast, stagnation (sometimes called "self-absorption") develops when individuals sense that they have done nothing for the next generation.

Middle-aged adults can develop generativity in a number of ways (Kotre, 1984). Through biological generativity, adults have offspring. Through parental generativity, adults nurture and guide children. Through work generativity, adults develop skills that are passed down to others. And through cultural generativity, adults create, renovate, or conserve some aspect of culture that ultimately survives (Lewis & Allen, 2017).

Adults promote and guide the next generation by parenting, teaching, leading, and doing things that benefit the community (Russo-Netzer & Moran, 2018). One of the participants in a study of aging said, "From twenty to thirty I learned how to get along with my wife. From thirty to forty I learned how to be a success at my job, and at forty to fifty I worried less about myself and more about the children" (Vaillant, 2002, p. 114). Generative adults commit themselves to the continuation and improvement of society as a whole through their connection to the next generation. Generative adults develop a positive legacy of the self and then offer it as a gift to the next generation.

Does research support Erikson's theory that generativity is an important dimension of middle age? Yes, it does (Dunlop, Bannon, & McAdams, 2017). In George Vaillant's (2002) longitudinal studies of aging, generativity (defined in this study as "taking care of the next generation") in middle age was more strongly related than intimacy to whether individuals would have an enduring and happy marriage at 75 to 80 years of age.

Other research also supports Erikson's (1968) emphasis on the importance of generativity in middle adulthood. In one study, Carol Ryff (1984) examined the views of women and men at different ages and found that middle-aged adults especially were concerned about generativity. In a longitudinal study of Smith College women, the desire for generativity increased as the participants aged from their thirties to their fifties (Stewart, Ostrove, & Helson, 2001) (see Figure 1). Also, in a recent study, participating in an intergenerational civic engagement program enhanced older

adults' perceptions of generativity (Gruenewald & others, 2016). Further, in another study, a higher level of generativity in midlife was linked to greater wisdom in late adulthood (Ardelt, Gerlach, & Vaillant, 2018).

**Levinson's Seasons of a Man's Life** In *The Seasons of a Man's Life* (1978), clinical psychologist Daniel Levinson reported the results of extensive interviews with 40 middle-aged men. The interviews were conducted with hourly workers, business executives, academic biologists, and novelists. Levinson bolstered his conclusions with information from the biographies of famous men and the development of memorable characters in literature. Although Levinson's major interest focused on midlife change, he described a number of stages and transitions during the period from 17 to 65 years of age, as shown in Figure 2. Levinson emphasizes that developmental tasks must be mastered at each stage.

At the end of one's teens, according to Levinson, a transition from dependence to independence should occur. This transition is marked by the formation of a dream—an image of the kind of life the youth wants to have, especially in terms of a career and marriage. Levinson sees the twenties as a novice phase of adult development. It is a time of reasonably free experimentation and of testing the dream in the real world. In early adulthood, the two major tasks to be mastered are exploring the possibilities for adult living and developing a stable life structure.

From about the ages of 28 to 33, a man goes through a transition period in which he must face the more serious question of determining his goals. During his thirties, he usually focuses on family and career development. In the later years of this period, he enters a phase of Becoming One's Own Man (or BOOM, as Levinson calls it). By age 40, he has reached a stable point in his career, has outgrown his earlier, more tenuous attempts at learning to become an adult, and now must look forward to the kind of life he will lead as a middle-aged adult.

According to Levinson, the transition to middle adulthood lasts about five years (ages 40 to 45) and requires the adult male to come to grips with four major conflicts that have existed in his life since adolescence: (1) being young versus being old, (2) being destructive versus being constructive, (3) being masculine versus being feminine, and (4) being attached to others versus being separated from them. Seventy to 80 percent of the men Levinson interviewed found the midlife transition tumultuous and psychologically painful, as many aspects of their lives came into question. According to Levinson, the success of the midlife transition rests on how effectively the individual reduces the polarities and accepts each of them as an integral part of his being.

Because Levinson interviewed middle-aged men, we can consider the data about middle adulthood more valid than the data about early adulthood. When individuals are asked to remember information about earlier parts of their lives, they may distort and forget things. The original Levinson data included no women, although Levinson (1996) reported that his stages, transitions, and the crisis of middle age hold for women as well as men. Levinson's work included no statistical analysis. However, the quality and quantity of the Levinson biographies make them outstanding examples of the clinical tradition.

**How Pervasive Are Midlife Crises?** Levinson (1978) views midlife as a crisis, arguing that the middle-aged adult is suspended between the past and the future, trying to cope with this gap that threatens life's continuity. George Vaillant (1977) has a different view. Vaillant's study—called the "Grant Study"—involved Harvard University men in their early thirties and in their late forties who initially had been interviewed as undergraduates. He concludes that just as adolescence is a time for detecting parental flaws and discovering the truth about childhood, the forties are a decade of reassessing and recording the truth about the adolescent and adulthood years. However, whereas Levinson sees midlife as a crisis, Vaillant maintains that only a minority of adults experience a midlife crisis:

Just as pop psychologists have reveled in the not-so-common high drama of adolescent turmoil, just so the popular press, sensing good copy, has made all too much of the midlife crisis. The term *midlife crisis* brings to mind some variation of the renegade minister who leaves behind four children and the congregation that loved him in order to drive off in a magenta Porsche with a 25-year-old striptease artiste. . . . As with adolescent turmoil, midlife crises are much rarer in community samples than in clinical samples. (pp. 222–223)

Late adult transition: Age 60 to 65

Middle adult transition: Age 40 to 45

Early adult transition: Age 17 to 22

## FIGURE 2

### LEVINSON'S PERIODS OF ADULT DEVELOPMENT.

According to Daniel Levinson, adulthood for men has three main stages that are surrounded by transition periods. Specific tasks and challenges are associated with each stage.

### developmental connection

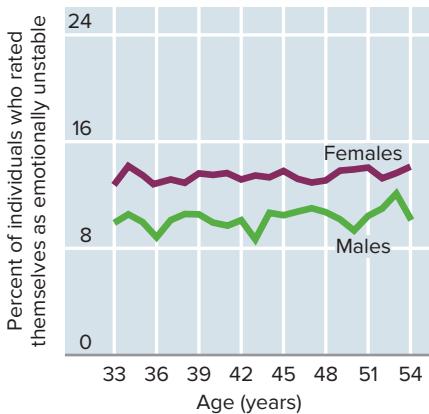

#### Personality

Erikson's early adulthood stage is intimacy versus isolation and his late adulthood stage is integrity versus despair. Connect to "Socioemotional Development in Early Adulthood" and "Socioemotional Development in Late Adulthood."

Midlife crises are greatly exaggerated in America.

—GEORGE VAILLANT

*Contemporary Psychologist, Harvard University*

**FIGURE 3**

**EMOTIONAL INSTABILITY AND AGE.** In one longitudinal study, the emotional instability of individuals was assessed from age 33 to age 54. No significant increase in emotional instability occurred during the middle-aged years.

Source: McCrae, R.R., & Costa, P.T. *Personality in adulthood*. New York: Guilford, 1990. Copyright ©1990 by Guilford. All rights reserved. Used with permission.

Thus, for most people midlife is not a crisis (Lachman, Teshale, & Agrigoroaei, 2015). Many cognitive skills, such as vocabulary, verbal memory, and inductive reasoning, peak in midlife, and many individuals reach the height of their career success in midlife (Schaie, 2016). Further, happiness and positive affect have an upward trajectory from early adulthood to late adulthood (Carstensen, 2015).

A number of research studies have documented that midlife is not characterized by pervasive crises:

- One study found that 26 percent of middle-aged U.S. adults said they had experienced a midlife crisis, but most attributed the crisis to negative life events rather than aging (Wethington, Kessler, & Pixley, 2004).
- A longitudinal study of more than 2,000 individuals found few midlife crises (McCrae & Costa, 1990; Siegler & Costa, 1999). In this study, the emotional instability of individuals did not significantly increase during their middle-aged years (see Figure 3).
- A study of individuals described as young adults (average age 19), middle-aged adults (average age 46), and older adults (average age 73) found that their ability to master their environment, autonomy, and personal relations improved during middle age (Keyes & Ryff, 1998) (see Figure 4).

Adult development experts are virtually unanimous in their belief that midlife crises have been exaggerated (Lachman, Teshale, & Agrigoroaei, 2015; Pudrovska, 2009). In sum:

- The stage theories place too much emphasis on crises in development, especially midlife crises.
- There often is considerable individual variation in the way people experience the stages, a topic that we will turn to next.

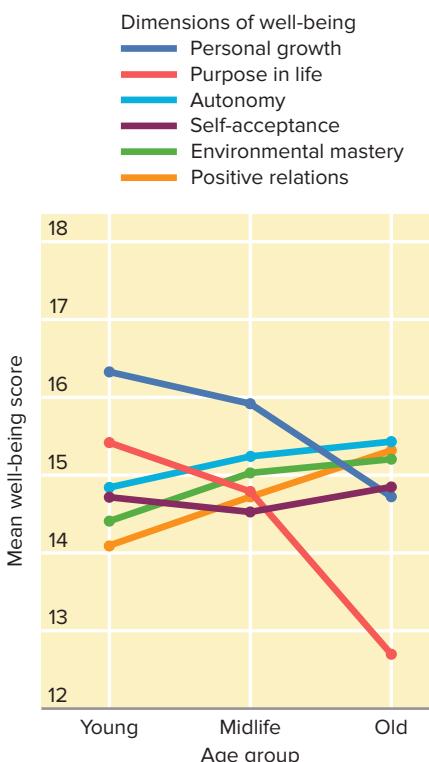

**Individual Variations** Stage theories focus on the universals of adult personality development as they try to pin down stages that all individuals go through in their adult lives. These theories do not adequately address individual variations in adult development. One extensive study of a random sample of 500 men at midlife, for example, found considerable individual variation among men (Farrell & Rosenberg, 1981). In the individual variations view, middle-aged adults interpret, shape, alter, and give meaning to their lives.

Some individuals may experience a midlife crisis in some contexts of their lives but not others (Lachman, 2004). For example, turmoil and stress may characterize a person's life at work even while things are going smoothly at home.

Researchers have found that in one-third of the cases in which individuals have reported going through a midlife crisis, the "crisis is triggered by life events such as a job loss, financial problems, or illness" (Lachman, 2004, p. 315). Let's now explore the role of life events in midlife development.

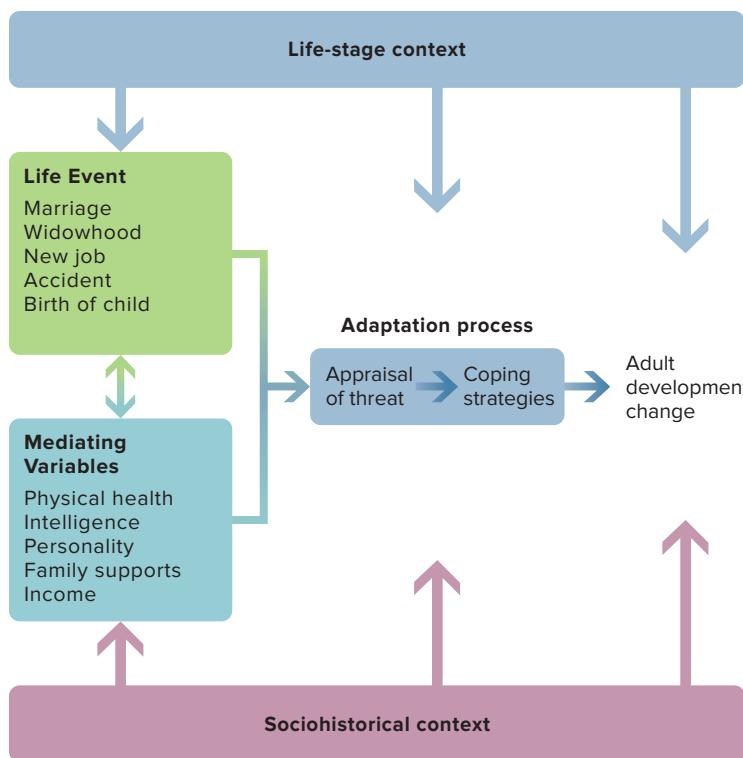

## THE LIFE-EVENTS APPROACH

Age-related stages represent one major way to examine adult personality development. A second major way to conceptualize adult personality development is to focus on life events (Kok & others, 2017; Oren & others, 2017; Patrick, Carney, & Nehrkorn, 2017; Pruchno, Heid, & Wilson-Genderson, 2017). In the early version of the life-events approach, life events were viewed as taxing circumstances for individuals, forcing them to change their personality (Holmes & Rahe, 1967). Events such as the death of a spouse, divorce, marriage, and so on were believed to involve varying degrees of stress, and therefore likely to influence the individual's development. One study found that stressful life events were associated with

**FIGURE 4**

**AGE AND WELL-BEING.** In one study, six dimensions of well-being (self-acceptance, positive relations, personal growth, purpose in life, environmental mastery, and autonomy) were assessed in three different age groups of individuals (young adults, middle-aged adults, and older adults). An increase or little change in most of the dimensions of well-being occurred during middle adulthood. Source: Keyes, C. L. M., & Ryff, C. D. "Generativity in adult lives: Social structure contours and quality of life consequences." In D.P. McAdams & E. de St. Aubin (Eds.), *Generativity and adult development: How and why we care for the next generation*. Washington, DC: American Psychological Association, 1998.

**FIGURE 5**  
**A CONTEMPORARY LIFE-EVENTS FRAMEWORK FOR INTERPRETING ADULT DEVELOPMENTAL CHANGE.**  
According to the contemporary life-events approach, the influence of a life event depends on the event itself, on mediating variables, on the life-stage and sociohistorical context, and on the individual's appraisal of the event and coping strategies.

cardiovascular disease in middle-aged women (Kershaw & others, 2014). And a recent meta-analysis found an association between stressful life events and autoimmune diseases, such as arthritis and psoriasis (Porcelli & others, 2016).

Today's life-events approach is more sophisticated. In the **contemporary life-events approach**, how life events influence the individual's development depends not only on the life event itself but also on mediating factors (such as physical health and family supports), the individual's adaptation to the life event (such as appraisal of the threat and coping strategies), the life-stage context, and the sociohistorical context (see Figure 5). For example, if individuals are in poor health and have little family support, life events are likely to be more stressful. And a divorce may be more stressful after many years of marriage when adults are in their fifties than when they have been married only several years and are in their twenties, a finding indicating that the life-stage context of an event makes a difference. The sociohistorical context also makes a difference. For example, adults may be able to cope more effectively with divorce today than in the 1950s because divorce has become more commonplace and accepted in today's society. Whatever the context or mediating variables, however, one individual may perceive a life event as highly stressful, whereas another individual may perceive the same event as a challenge.

Although the life-events approach offers valuable insights for understanding adult development, it has its drawbacks. One drawback is that the life-events approach places too much emphasis on change. It does not adequately recognize the stability that, at least to some degree, characterizes adult development.

Another drawback is that it may not be life's major events that are the primary sources of stress, but our daily experiences (Du, Derkx, & Bakker, 2018; Keles & others, 2016; Koffer & others, 2018; Louch & others, 2017). Enduring a boring but tense job or living in poverty does not show up on scales of major life events. Yet the everyday pounding from these conditions can add up to a highly stressful life and eventually lead to illness. Greater insight into the source of life's stresses might come from focusing more on daily hassles and daily uplifts (Sarid & others, 2018; Scott & others, 2018; Smyth & others, 2018). Researchers have found that young and middle-aged adults experience a greater daily frequency of stressors than older adults do (Almeida & Horn, 2004). In one study, healthy older adult women 63 to 93 years of age reported their daily experiences over the course of one week (Charles & others, 2010). In this study, the older a woman was, the fewer stressors and less frequent negative affect she reported. Also, researchers have found that greater emotional reactivity to daily stressors was linked to increased risk of reporting a chronic physical health condition and anxiety/mood disorders 10 years later (Charles & others, 2013; Piazza & others, 2013). And a

#### contemporary life-events approach

Approach emphasizing that how a life event influences the individual's development depends not only on the life event but also on mediating factors, the individual's adaptation to the life event, the life-stage context, and the sociohistorical context.

Daily Hassles	Percentage of Times Checked
Concerns about weight	52.4
Health of family member	48.1
Rising prices of common goods	43.7
Home maintenance	42.8
Too many things to do	38.6
Misplacing or losing things	38.1
Yardwork/outside home maintenance	38.1
Property, investment, or taxes	37.6
Crime	37.1
Physical appearance	35.9

Daily Uplifts	Percentage of Times Checked
Relating well with your spouse or lover	76.3
Relating well with friends	74.4
Completing a task	73.3
Feeling healthy	72.7
Getting enough sleep	69.7
Eating out	68.4
Meeting your responsibilities	68.1
Visiting, phoning, or writing someone	67.7
Spending time with family	66.7
Home (inside) pleasing to you	65.5

**FIGURE 6**

**THE TEN MOST FREQUENT DAILY HASSLES AND UPLIFTS OF MIDDLE-AGED ADULTS OVER A NINE-MONTH PERIOD.**

*How do these hassles and uplifts compare with your own?*

### developmental connection

#### Stress

Adolescence has been characterized too negatively, dating from Hall's storm and stress view of adolescents. Connect to "Physical and Cognitive Development in Adolescence."

study of adults (mean age 57 years) revealed that higher levels of daily stressors were associated with increased cortisol output (cortisol is the body's primary stress hormone), especially if the stressors included arguments and other problems at home (Stawski & others, 2013). Researchers have also found that stressful daily hassles are linked to increased anxiety and lower physical well-being (Falconier & others, 2015).

One study found that the daily hassles most frequently reported by college students were wasting time, concerns about meeting high standards, and being lonely (Kanner & others, 1981). Among the uplifts reported most frequently by the college students were entertainment, getting along well with friends, and completing a task. In this same study, the daily hassles reported most often by middle-aged adults were concerns about weight and the health of a family member, while their most frequently reported daily uplifts involved relating well with a spouse or lover, or a friend (see Figure 6). And the middle-aged adults were more likely than the college students to report that their daily hassles involved economic concerns (rising prices and taxes, for example).

The manner in which different stressors affect health varies—life events often produce prolonged arousal whereas daily stressors are linked to spikes in arousal (Piazza & others, 2010). Consider caring for a spouse who has Alzheimer disease. In this case, a life event (spouse diagnosed with an incurable disease) produces chronic stress for the caregiver, which also is linked to the daily stressors involved in caring for the individual.

Critics of the daily hassles approach argue that some of the same problems involved with life-events scales occur when daily hassles are assessed. For example, knowing about an adult's daily hassles tells us nothing about physical changes, about how the individual copes with hassles, or about how the individual perceives hassles.

## STRESS AND PERSONAL CONTROL IN MIDLIFE

As we have seen, there is conclusive evidence that midlife is not a time when a majority of adults experience a tumultuous crisis, but if they do experience a midlife crisis it is often linked to stressful life events. Do middle-aged adults experience stress differently from young adults and older adults?

**Stress, Personal Control, and Age** Margie Lachman and her colleagues (2016) recently described how personal control changes when individuals move into middle age. In their view, middle age is a time when a person's sense of control is frequently challenged by many demands and responsibilities, as well as physical and cognitive aging. By contrast, young people are more likely to have a sense of invulnerability, to be unrealistic about their personal control, and to be unaware of the aging process. Many young people focus primarily on self pursuits and don't have to worry much about responsibilities for others. But in middle age, less attention is given to self pursuits and more to responsibility for others, including those younger and older than they are. According to Lachman and her colleagues (2016), how the midlife years play out is largely in one's own hands, which can be stressful as individuals are faced with taking on and juggling responsibilities in different areas of their lives.

One study using daily diaries over a one-week period found that both young and middle-aged adults had more days that were stressful and that were characterized by multiple stresses than older adults (Almeida & Horn, 2004). In this study, although young adults experienced daily stressors more frequently than middle-aged adults, middle-aged adults experienced more "overload" stressors that involved juggling too many activities at once. Another study also revealed that middle-aged and older adults showed a smaller increase in psychological distress to interpersonal stressors than did younger adults, and middle-aged adults were less physically reactive to work stressors than were younger adults (Neupert, Almeida, & Charles, 2007).

To what extent do middle-aged adults perceive that they can control what happens to them? Researchers have found that on average a sense of personal control peaks in midlife

and then declines (Lachman, 2006; Lachman, Agrigoroaei, & Hahn, 2016; Lachman, Teshale, & Agrigoroaei, 2015; Robinson & Lachman, 2017). In one study, approximately 80 percent of the young adults (25 to 39 years of age), 71 percent of the middle-aged adults (40 to 59 years of age), and 62 percent of the older adults (60 to 75 years of age) reported that they were often in control of their lives (Lachman & Firth, 2004). However, some aspects of personal control increase with age while others decrease (Lachman, Neupert, & Agrigoroaei, 2011). For example, middle-aged adults feel a greater sense of control over their finances, work, and marriage than younger adults but less control over their sex life and their children (Lachman & Firth, 2004).

**Stress and Gender** Women and men differ in the way they experience and respond to stressors (Taylor, 2015, 2018). Women are more vulnerable to social stressors such as those involving romance, family, and work. For example, women experience higher levels of stress than men do when things go wrong in romantic and marital relationships. Women also are more likely than men to become depressed when they encounter stressful life events such as divorce or the death of a friend. A recent study found that in coping with stress, women were more likely than men to seek psychotherapy, talk to friends about the stress, read a self-help book, take prescription medication, and engage in comfort eating (Liddon, Kingerlee, & Barry, 2017). In this study, in coping with stress men were more likely than women to attend a support group meeting, have sex or use pornography, try to fix problems themselves, and not admit to having problems.

When men face stress, they are more likely to respond in a **fight-or-flight** manner—to become aggressive, withdraw from social contact, or drink alcohol. By contrast, according to Shelley Taylor and her colleagues (2011a, b, c; 2015, 2018), when women experience stress, they are more likely to engage in a **tend-and-befriend** pattern, seeking social alliances with others, especially friends. Taylor argues that when women experience stress an influx of the hormone *oxytocin*, which is linked to nurturing in animals, is released.

How do women and men differ in the way they experience and respond to stressors?

## CONTEXTS OF MIDLIFE DEVELOPMENT

Both Sarah and Wanda, whose stories appeared at the beginning of this chapter, are working mothers. In almost every other way, however, their lives could scarcely be more different. Why? Part of the answer might lie in the different contexts of their lives. The contemporary life-events approach (like Bronfenbrenner's theory) highlights the importance of the complex setting of our lives—of everything from our income and family supports to our sociohistorical circumstances. Let's examine how three aspects of the contexts of life influence development during middle adulthood: historical contexts (cohort effects), gender, and culture.

**Historical Contexts (Cohort Effects)** Some developmentalists conclude that changing historical times and different social expectations influence how different cohorts—groups of individuals born in the same year or time period—move through the life span (Schaie, 2010, 2013, 2016). Bernice Neugarten (1986) argues that our values, attitudes, expectations, and behaviors are influenced by the period in which we live. For example, individuals born during the difficult times of the Great Depression may have a different outlook on life from those born during the optimistic 1950s, says Neugarten.

Neugarten (1986) holds that the social environment of a particular age group can alter its **social clock**—the timetable on which individuals are expected to accomplish life's tasks, such as getting married, having children, or establishing themselves in a career. Social clocks provide guides for our lives; individuals whose lives are not synchronized with these social clocks find life to be more stressful than those who are on schedule, says Neugarten. For example, the fact that Sarah's pregnancy occurred when she was a teenager probably increased the stressfulness of that pregnancy. Neugarten argues that today there is much less agreement than in the past on the right age or sequence for the occurrence of major life events such as having children or retiring. Indeed, one study found that between the late 1950s and the late 1970s, there was a dramatic decline in adults' beliefs that there is a "best age" for major life events and achievements (Passuth, Maines, & Neugarten, 1984) (see Figure 7).

### developmental connection

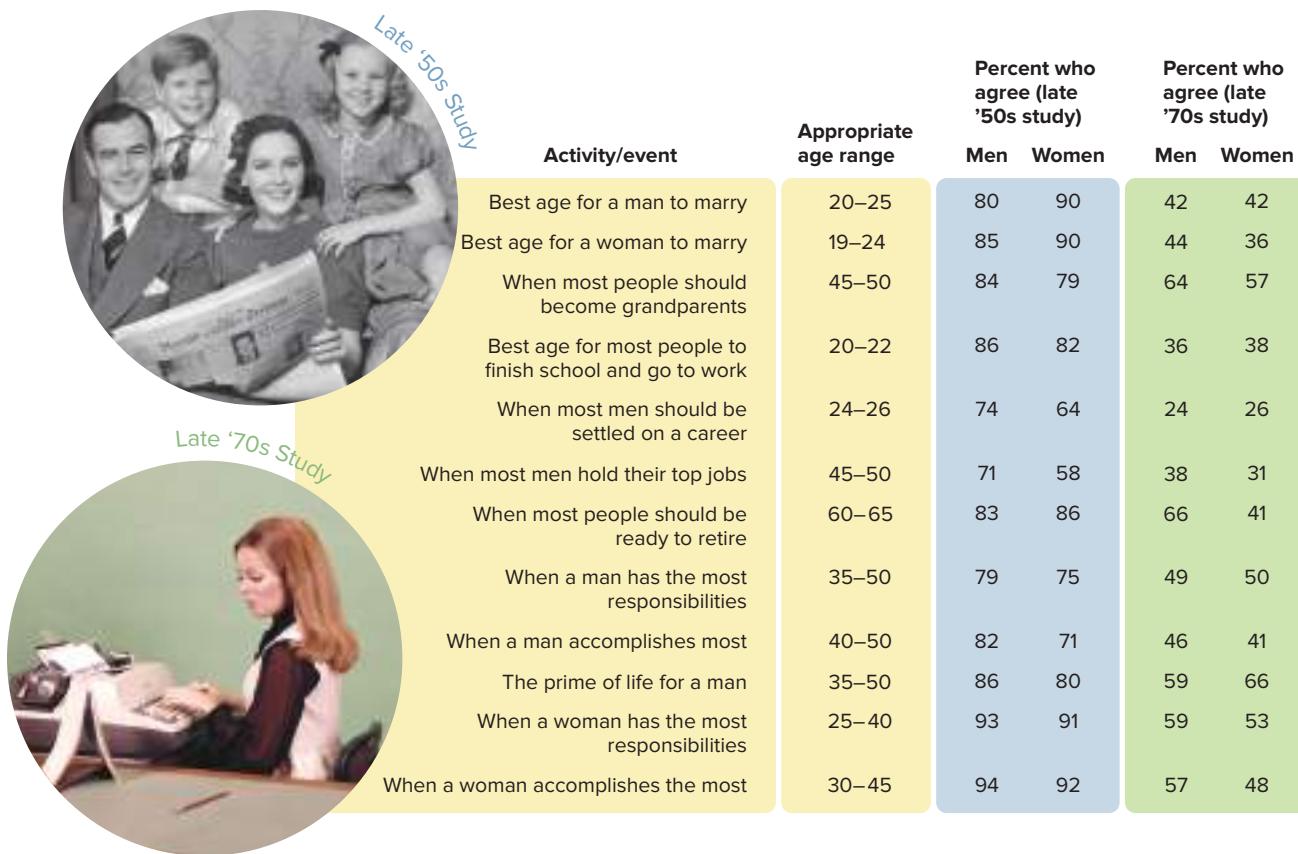

#### Research Methods

Cohort effects have also been described as normative, history-graded influences. Connect to "Introduction."

**fight-or-flight** The view that when men experience stress, they are more likely to engage in a fight-or-flight pattern, as reflected in being aggressive, withdrawing from social contact, or drinking alcohol.

**tend-and-befriend** Taylor's view that when women experience stress, they are likely to engage in a tend-and-befriend pattern, seeking social alliances with others, especially female friends.

**social clock** The timetable according to which individuals are expected to accomplish life's tasks, such as getting married, having children, or establishing themselves in a career.

**FIGURE 7**

#### INDIVIDUALS' CONCEPTIONS OF THE BEST AGE FOR MAJOR LIFE EVENTS AND ACHIEVEMENTS: LATE 1950S AND LATE 1970S.

**1970S.** *What do you think is the best age to experience each of these major life events and accomplishments?*

©George Marks/Getty Images; ©H. Armstrong Roberts/Retrofile/Getty Images

Critics say the stage theories of adult development reflect a male bias by emphasizing career choice and achievement, and that they do not adequately address women's concerns about relationships, interdependence, and caring. The stage theories assume a normative sequence of development, but as women's roles have become more varied and complex, determining what is normative is difficult. *What kinds of changes have taken place in middle-aged women's lives in recent years?*

©Corbis/VCG/Getty Images

**Gender Contexts** Critics say that the stage theories of adult development have a male bias. For example, the central focus of stage theories is on career choice and work achievement, which historically have dominated men's life choices and life chances more than women's. The stage theories do not adequately address women's concerns about relationships, interdependence, and caring (Gilligan, 1982). The adult stage theories have also placed little importance on childbearing and child rearing. Women's family roles are complex and often have a higher salience in their lives than in men's lives. The role demands that women experience in balancing career and family are usually not experienced as intensely by men.

Should midlife and the years beyond be feared by women as a time of declining youth and opportunity? Or is middle adulthood a new prime of life, a time for renewal, for shedding preoccupations with a youthful appearance and body, and for seeking new challenges, valuing maturity, and enjoying change?

In one study, the early fifties were indeed a new prime of life for many women (Mitchell & Helson, 1990). In this sample of 700 women aged 26 to 80, women in their early fifties most often described their lives as "first-rate." Conditions that distinguished the lives of women in their early fifties from those of women in other age periods included more "empty nests," better health, higher income, and more concern for parents. Women in their early fifties showed confidence, involvement, security, and breadth of personality.

In sum, the view that midlife is a negative age period for women is stereotypical, as so many perceptions of age periods are. Midlife is a diversified, heterogeneous period for women, just as it is for men.

**Cultural Contexts** In many cultures, especially nonindustrialized cultures, the concept of middle age is not very clear, or in some cases is absent. It is common in nonindustrialized societies to describe individuals as young or old but not as middle-aged (Grambs, 1989). Some cultures have no words for “adolescent,” “young adult,” or “middle-aged adult.”

Consider the Gusii culture, located in the African country of Kenya. The Gusii divide the life course differently for females and males (LeVine, 1979): females: (1) infant, (2) uncircumcised girl, (3) circumcised girl, (4) married woman, and (5) female elder; males: (1) infant, (2) uncircumcised boy, (3) circumcised boy warrior, and (4) male elder. Thus, movement from one status to the next is due primarily to life events, not age, in the Gusii culture.

Although the Gusii do not have a clearly labeled midlife transition, some of the Gusii adults do reassess their lives around the age of 40. At this time, these Gusii adults examine their current status and the limited time they have remaining in their lives. Their physical strength is decreasing, and they know they cannot farm their land forever, so they seek spiritual powers by becoming ritual practitioners or healers. As in the American culture, however, a midlife crisis in the Gusii culture is the exception rather than the rule.

Gusii dancers perform on habitat day in Nairobi, Kenya. Movement from one status to another in the Gusii culture is due primarily to life events, not age. The Gusii do not have a clearly labeled midlife transition.

## Review Connect Reflect

**LG1** Describe personality theories and socioemotional development in middle adulthood.

### Review

- What are some theories of adult stages of development?
- What is the life-events approach?
- How do middle-aged adults experience stress and personal control differently from young and older adults?
- How do contexts influence midlife development?

### Connect

- In this section, you read that some researchers criticize the stage theories

of adult development as having a male bias. What have you learned about gender bias in research?

### Reflect Your Own Personal Journey of Life

- Which approach makes more sense—adult stage or life events—in explaining your own development as you go through adulthood? Or do you think both approaches should be considered in understanding your development as an adult? Explain your answer.

## 2 Stability and Change

**LG2** Discuss stability and change in development during middle adulthood, as reflected in longitudinal studies.

Longitudinal Studies

Conclusions

Sarah’s adult life, described in the chapter opening, has followed a painful path. Were her sorrows an inevitable result of how she learned to cope with problems earlier in life? Is it possible for her, in middle age, to change her coping strategies or how she relates to other people?

## LONGITUDINAL STUDIES

A number of longitudinal studies have assessed stability and change in the personalities of individuals at different points in their lives (Borghuis & others, 2017; Chopik & Kitayama, 2018; Fajkowska, 2017; Graham & others, 2017; Hampson & Edmonds, 2018; Hengartner & Yamanaka-Altenstein, 2017). We will examine four longitudinal studies that can help us understand the extent to which there is stability or change in adult development: Costa and McCrae’s Baltimore Study, the Berkeley Longitudinal Studies, Helson’s Mills College Study, and Vaillant’s studies.

**Costa and McCrae’s Baltimore Study** A major, ongoing study of adult personality development is being conducted by Paul Costa and Robert McCrae (1998, 2013; McCrae &

### developmental connection

#### Life-Span Perspective

The extent to which development is characterized by stability and/or change is one of the key issues in the study of life-span development. Connect to “Introduction.”

**FIGURE 8**

**THE BIG FIVE FACTORS OF PERSONALITY.** Each of the broad supertraits encompasses more narrow traits and characteristics. Use the acronym OCEAN to remember the Big Five personality factors: openness, conscientiousness, extraversion, agreeableness, and neuroticism.

Costa, 2003, 2006). They focus on what are called the **Big Five factors of personality**, which are openness to experience, conscientiousness, extraversion, agreeableness, and neuroticism (emotional stability); these personality factors are described in Figure 8. (Notice that if you create an acronym from these factor names, you will get the word OCEAN.) A number of research studies point toward these factors as important dimensions of personality (Graham & others, 2017; Hampson & Edmonds, 2018; Hill & Roberts, 2016; Roberts & Damian, 2017; Roberts & others, 2014, 2017; Strickhouser, Zell, & Krizan, 2017).

Using their five-factor personality test, Costa and McCrae (1995, 2000) studied approximately 1,000 college-educated men and women ages 20 to 96, assessing the same individuals over many years. Data collection began in the 1950s and is ongoing. Costa and McCrae concluded that considerable stability occurs in the five personality factors—emotional stability, extraversion, openness, agreeableness, and conscientiousness. However, more recent research indicates greater developmental changes in the five personality factors in adulthood (Graham & Lachman, 2014; Hill & Roberts, 2016; Lucas & Donnellan, 2011; Soto & others, 2011; Roberts & others, 2017). For example, a recent study found that emotional stability, extraversion, openness, and agreeableness were lower in early adulthood, peaked between 40 and 60 years of age, and decreased in late adulthood, while conscientiousness showed a continuous increase from early adulthood to late adulthood (Specht, Egloff, & Schukle, 2011). Most research studies indicate that the greatest change occurs in early adulthood (Hill, Allemand, & Roberts, 2014; Hill & Roberts, 2016; Lucas & Donnellan, 2011; Roberts, Donnellan, & Hill, 2013).

Further evidence for the importance of the Big Five factors indicates that they are related to such important aspects of a person's life as health, intelligence and cognitive functioning, achievement and work, and relationships (Bertrand, Graham, & Lachman, 2013; English & Carstensen, 2014; Hampson & others, 2015; Hill & others, 2014; Roberts & Damian, 2017). The following research supports these links:

- *Openness to experience.* Individuals high on openness to experience are more likely to have better health and well-being (Strickhouser, Zell, & Krizan, 2017), be tolerant (McCrae & Sutin, 2009), have superior cognitive functioning, achievement, and IQ across the life span (Briley, Domiteaux, & Tucker-Drob, 2014), show creative achievement in the arts (Kaufman & others, 2016), experience less negative affect to stressors (Leger & others, 2016), have greater success as entrepreneurs (Zhao, Seibert, & Lumpkin, 2010), and to eat more fruits and vegetables (Conner & others, 2017).
- *Conscientiousness.* Individuals high in conscientiousness often do well in a variety of life domains (Boyce, Wood, & Ferguson, 2016; Mike & others, 2015; Roberts & Damian, 2018; Roberts & Hill, 2017). For example, they are more likely to live longer (Graham & others, 2017), have better health and less stress (Strickhouser, Zell, & Krizan, 2017), engage in superior problem-focused coping (Sesker & others, 2016), maintain better-quality friendships (Jensen-Campbell & Malcolm, 2007), achieve higher grade point averages in college (McCabe & Oswald, 2013), be more academically successful in medical school (Sobowale & others, 2018), be more successful at accomplishing goals (McCabe & Fleeson, 2016), engage in less substance abuse (Walton & Roberts, 2004), experience less negative affect to stressors (Leger & others, 2016), gamble less (Hwang & others, 2012), be less likely to have an alcohol addiction (Raketic & others, 2017), experience less cognitive decline in aging (Luchetti & others, 2016),

### developmental connection

#### Personality

The Big Five factors are linked to longevity. Connect to “Socioemotional Development in Late Adulthood.”

**Big Five factors of personality** Emotional stability (neuroticism), extraversion, openness to experience, agreeableness, and conscientiousness.

and are less likely to be characterized by Internet addiction (Kircaburun & Griffiths, 2018; Zhou & others, 2017).

- **Extraversion.** Individuals high in *extraversion* are more likely than others to live longer (Graham & others, 2017), engage in social activities (Emmons & Diener, 1986), be more satisfied in relationships (Toy, Nai, & Lee, 2016), have fewer sleep problems (Hintsanen & others, 2014), show less negative affect to stressors (Leger & others, 2016), and have a more positive sense of well-being in the future (Soto, 2015).
- **Agreeableness.** People who are high in agreeableness are more likely to live longer (Graham & others, 2017), be generous and altruistic (Caprara & others, 2010), have more satisfying romantic relationships (Donnellan, Larsen-Rife, & Conger, 2005), view other people positively (Wood, Harms, & Vazire, 2010), show more positive affect to stressors (Leger & others, 2016), lie less about themselves in online dating profiles (Hall & others, 2010), and have a lower risk of dementia (Terracciano & others, 2017).
- **Neuroticism.** People high in neuroticism are more likely to die at a younger age (Graham & others, 2017), have worse health and report having more health complaints (Strickhouser, Zell, & Krizan, 2017), feel negative emotion than positive emotion in daily life, experience more lingering negative states, and have more stressor-related negative affect (Leger & others, 2016; Widiger, 2009), be more drug dependent (Raketic & others, 2017; Valero & others, 2014), have a higher coronary heart disease risk (Lee & others, 2014), have a lower sense of well-being 40 years later (Gale & others, 2013), and have a higher risk of dementia (Terracciano & others, 2017). Also, research indicates that a combination of a higher level of conscientiousness and a lower level of neuroticism is linked to better health (Turiano & others, 2013).

Another important personality trait-like characteristic is *optimism*, which involves having a positive outlook on the future and minimizing problems. Optimism is often referred to as a style of thinking. Researchers increasingly are finding that optimism is linked to better adjustment, improved health, and increased longevity (Boelen, 2015; Kolokotroni, Anagnostopoulos, & Hantzi, 2018). A recent study revealed that college students who were more pessimistic had more anxious mood and stress symptoms (Lau & others, 2017). Another study involving adults 50 years of age and older revealed that being optimistic and having an optimistic spouse were both associated with better health and physical functioning (Kim, Chopik, & Smith, 2014). Further, another study of married couples found that the worst health outcomes occurred when both spouses decreased in optimism across a four-year time frame (Chopik, Kim, & Smith, 2018). In another study, a higher level of optimism following an acute coronary event was linked to engaging in more physical activity and experiencing fewer cardiac readmissions (Huffman & others, 2016). Also, in a recent study, lonely individuals who were optimistic had a lower suicide risk than their counterparts who were more pessimistic (Chang & others, 2018). And a recent research review concluded that the influence of optimism on positive outcomes for people who have chronic diseases (such as cancer, cardiovascular disease, and respiratory disease) may involve (a) a possible direct effect on the neuroendocrine system and on immune system function, and/or (b) an indirect effect on health outcomes by increasing protective health behaviors, adaptive coping strategies, and positive mood (Avvenuti, Baiardini, & Giardini, 2016).

**Berkeley Longitudinal Studies** In the Berkeley Longitudinal Studies, more than 500 children and their parents were initially studied in the late 1920s and early 1930s. The book *Present and Past in Middle Life* (Eichorn & others, 1981) profiles these individuals as they became middle-aged. The results from early adolescence through a portion of midlife did not support either extreme in the debate over whether personality is characterized by stability or change. Some characteristics were more stable than others, however. The most stable characteristics were the degree to which individuals were intellectually oriented, self-confident, and open to new experiences. The characteristics that changed the most included the extent to which the individuals were nurturant or hostile and whether or not they had good self-control.

John Clausen (1993), one of the researchers in the Berkeley Longitudinal Studies, stresses that too much attention has been given to discontinuities for all members of the human species, as exemplified in the adult stage theories. He points out that some people experience recurrent crises and undergo substantial changes over the life course, whereas others have more stable, continuous lives entailing very little change.

Based on their study of middle-aged women, Ravenna Helson and her colleagues described the women as experiencing a midlife consciousness rather than a midlife crisis. *What were some other findings in the Mills College study?*

©Tom Merton/Getty Images

Characteristics at age 50 have been linked to health and happiness at age 75 to 80. In a longitudinal study, characteristics at age 50 were related to whether individuals were happy-well, sad-sick, or dead at age 75 to 80 (Vaillant, 2002). *In Vaillant's longitudinal research, which characteristics at age 50 predicted better health and well-being at 75 to 80?*

©Ariel Skelly/Getty Images

**Helson's Mills College Study** Another longitudinal investigation of adult personality development was conducted by Ravenna Helson and her colleagues (George, Helson, & John, 2011; Helson, 1997; Helson & Wink, 1992; Stewart, Ostrove, & Helson, 2001). They initially studied 132 women who were seniors at Mills College in California in the late 1950s and then studied them again when they were in their thirties, forties, and fifties. Helson and her colleagues distinguished three main groups among the Mills women: family-oriented, career-oriented (whether or not they also wanted families), and those who followed neither path (women without children who pursued only low-level work).

During their early forties, many of the women shared the concerns that stage theorists such as Levinson found in men: concern for young and old, introspectiveness, interest in roots, and awareness of limitations and death. However, the researchers in the Mills College Study concluded that rather than being in a midlife crisis, the women were experiencing *midlife consciousness*. The researchers also discovered that commitment to the tasks of early adulthood—whether to a career or family (or both)—helped women learn to control their impulses, develop interpersonal skills, become independent, and work hard to achieve goals. Women who did not commit themselves to one of these lifestyle patterns faced fewer challenges and did not develop as fully as the other women did (Rosenfeld & Stark, 1987).

In the Mills College Study, some women moved toward becoming “pillars of society” in their early forties to early fifties. Menopause, caring for aging parents, and an empty nest were not associated with an increase in responsibility and self-control (Helson & Wink, 1992).

**George Vaillant's Studies** Longitudinal studies by George Vaillant help us explore a question that differs somewhat from the topics examined by the studies described so far: Does personality at middle age predict what a person's life will be like in late adulthood? Vaillant (2002) has conducted three longitudinal studies of adult development and aging: (1) a sample of 268 socially advantaged Harvard graduates born in about 1920 (called the “Grant Study”); (2) a sample of 456 socially disadvantaged inner-city men born in about 1930; and (3) a sample of 90 middle-SES, intellectually gifted women born in about 1910. These individuals have been assessed numerous times (in most cases, every two years), beginning in 1938 and continuing today for those who are still living. The main assessments involve extensive interviews with the participants, their parents, and teachers.

Vaillant categorized 75- to 80-year-olds as “happy-well,” “sad-sick,” or “dead.” He used data collected from these individuals when they were 50 years of age to predict which categories they were likely to end up in at 75 to 80 years of age. Alcohol abuse and smoking at age 50 were the best predictors of which individuals would be dead at 75 to 80 years of age. Factors at age 50 that were linked with being in the “happy-well” category at 75 to 80 years of age included getting regular exercise, avoiding being overweight, being well educated, having a stable marriage, being future-oriented, being thankful and forgiving, empathizing with others, being active with other people, and having good coping skills.

Wealth and income at age 50 were not linked with being in the “happy-well” category at 75 to 80 years of age. Generativity in middle age (defined as “taking care of the next generation”) was more strongly related than intimacy to whether individuals would have an enduring and happy marriage at 75 to 80 years of age (Vaillant, 2002).

The results for one of Vaillant's studies, the Grant Study of Harvard men, indicate that when individuals at 50 years of age were not heavy smokers, did not abuse alcohol, had a stable marriage, exercised, maintained a normal weight, and had good coping skills, they were more likely to be alive and happy at 75 to 80 years of age.

## CONCLUSIONS

What can be concluded about stability and change in regard to personality development during the adult years? There is increasing evidence that personality traits continue to change during the adult years, even into late

adulthood (Chopik & Kitayama, 2018; Hill & Roberts, 2016; Nye & others, 2016; Roberts & others, 2017). However, in a meta-analysis of 92 longitudinal studies, the greatest change in personality traits occurred in early adulthood—from about 20 to 40 years of age (Roberts, Walton, & Viechtbauer, 2006).

Thus, people show more stability in their personality when they reach midlife than they did when they were younger adults (Hill & Roberts, 2016; Nye & others, 2016; Roberts, Donnellan, & Hill, 2013). These findings support what is called a *cumulative personality model of personality development*, which states that with time and age people become more adept at interacting with their environment in ways that promote increased stability of personality (Caspi & Roberts, 2001; Hill & Roberts, 2016).

This does not mean that change is absent throughout middle and late adulthood. Ample evidence shows that social contexts, new experiences, and sociohistorical changes can affect personality development, but the changes in middle and late adulthood are usually not as great as those in early adulthood (Ayoub & Roberts, 2018; Hill & Roberts, 2016; Mroczek, Spiro, & Griffin, 2006; Quoidbach, Gilbert, & Wilson, 2013). In a recent research review, the personality trait that changed the most as a result of psychotherapy intervention was emotional stability, followed by extraversion (Roberts & others, 2017). In this review, the personality traits of individuals with anxiety disorders changed the most and those with substance use disorders the least.

In general, changes in personality traits across adulthood also occur in a positive direction. Over time, “people become more confident, warm, responsible, and calm” (Roberts & Mroczek, 2008, p. 33). Such positive changes equate with becoming more socially mature.

In sum, recent research contradicts the old view that stability of personality begins to set in at about 30 years of age (Ayoub & Roberts, 2018; Donnellan, Hill, & Roberts, 2015; Hill & Roberts, 2016; Roberts & Damian, 2017; Roberts & others, 2017; Shanahan & others, 2014). Although there are some consistent developmental changes in the personality traits of large numbers of people, at the individual level people can show unique patterns of personality traits—and these patterns often reflect life experiences related to themes of their particular developmental period (Roberts & Mroczek, 2008). For example, researchers have found that individuals who are in a stable marriage and a solid career track become more socially dominant, conscientious, and emotionally stable as they go through early adulthood (Roberts & Wood, 2006). And for some of these individuals there is greater change in their personality traits than for other individuals (Hill & Roberts, 2016; Roberts, Donnellan, & Hill, 2013).

## Review Connect Reflect

**LG2** Discuss stability and change in development during middle adulthood, as reflected in longitudinal studies.

### Review

## 3 Close Relationships

**LG3** Identify some important aspects of close relationships in middle adulthood.

Love and Marriage at Midlife

The Empty Nest and Its Refilling

Sibling Relationships and Friendships

Grandparenting

Intergenerational Relationships

There is a consensus among middle-aged Americans that a major component of well-being involves positive relationships with others, especially parents, spouse, and offspring (Blieszner & Roberto, 2012a, b; Markus & others, 2004). To begin our examination of midlife relationships, let’s explore love and marriage in middle-aged adults.

What characterizes marriage in middle adulthood?

©absolut/Shutterstock

## LOVE AND MARRIAGE AT MIDLIFE

Two major forms of love are romantic love and affectionate love. The fires of romantic love are strong in early adulthood. Affectionate, or companionate, love increases during middle adulthood. That is, physical attraction, romance, and passion are more important in new relationships, especially in early adulthood. Security, loyalty, and mutual emotional interest become more important as relationships mature, especially in middle adulthood (Crowley, 2018).

**Marriage** One study revealed that marital satisfaction increased in middle age (Gorchoff, John, & Helson, 2008). Some of the marriages that were difficult and rocky during early adulthood improved during middle adulthood. Although the partners may have lived through a great deal of turmoil, they eventually discovered a deep and solid foundation on which to anchor their relationship. In middle adulthood, marital partners may have fewer financial worries, less housework and chores, and more time with each other. Middle-aged partners are more likely to view their marriage as positive if they engage in mutual activities. Also, a recent study found that middle-aged married individuals had a lower likelihood of work-related health limitations (Lo, Cheng, & Simpson, 2016). And another recent study of middle-aged adults revealed that positive marital quality was linked to better health for both spouses (Choi, Yorgason, & Johnson, 2016).

Most individuals in midlife who are married voice considerable satisfaction with being married. In a large-scale study of individuals in middle adulthood, 72 percent of those who were married said their marriage was either “excellent” or “very good” (Brim, 1999). Possibly by middle age, many of the worst marriages already have dissolved. However, a recent study revealed that married and partnered middle-aged adults were more likely to view their relationships with ambivalence or indifference than their late adulthood counterparts (Windsor & Butterworth, 2010).

**Divorce** What trends characterize divorce in U.S. middle-aged adults? In a recent analysis that compared divorce rates for different age groups in 1990 to 2015, the divorce rate decreased for young adults but increased for middle-aged and older adults (Stepler, 2017):

<u>25 to 39 years</u>	<u>40 to 49 years</u>	<u>50+ years</u>
-21 percent	+14 percent	+109 percent

This recent increase in divorce among middle-aged adults has led to divorce in middle adulthood being labeled “gray divorce” when it occurs after 50 years of age (Crowley, 2018; Lin & others, 2018). What accounts for this increase in divorce among middle-aged and older adults? One explanation is the changing view of women, who initiate approximately 60 percent of the divorces after 40 years of age. Compared with earlier decades, divorce has less stigma for women and they are more likely to leave an unhappy marriage. Also compared with earlier decades, more women are employed and are less dependent on their husband’s income. Another explanation involves the increase in remarriages, in which the divorce rate is 2½ times as high as it is for couples in first marriages.

A survey by AARP (2004) of 1,148 people between the ages of 40 and 79 who were divorced at least once in their forties, fifties, or sixties found that staying married because of their children was by far the main reason many people took so long to become divorced. Despite the worry and stress involved in going through a divorce, three out of four of the divorcees said they had made the right decision to dissolve their marriage and reported a positive outlook on life. Sixty-six percent of the divorced women said they had initiated the divorce, compared with only 41 percent of the divorced men. The divorced women were much more afraid of having financial problems (44 percent) than were the divorced men (11 percent). Following are the main reasons the middle-aged and older adult women cited for their divorce: (1) verbal, physical, or emotional abuse (23 percent); (2) alcohol or drug abuse (18 percent); and (3) cheating (17 percent). The main reasons the middle-aged and older men cited for their divorce were (1) no obvious problems, just fell out of love (17 percent); (2) cheating (14 percent); and (3) different values, lifestyles (14 percent).

In a recent study of the antecedents of “gray divorce,” factors traditionally associated with divorce in young adults also were reflected in the divorce of adults 50 years and older

What are some ways that divorce might be more positive or more negative in middle adulthood than in early adulthood?

©Stock4B/Getty Images

(Crowley, 2018; Lin & others, 2018). Divorce was more likely to occur in these older adults when they had been married fewer years, their marriage was of lower quality (less marital satisfaction, for example), they did not own a home, and they had financial problems. Factors that were not linked to divorce in these older adults were the onset of an empty nest, the wife's or husband's retirement, and whether the wife or husband had a chronic health condition.

Also, in a recent Swiss study of middle-aged adults, single divorcees were more lonely and less resilient than their married and remarried counterparts (Knopfli & others, 2016). In the same study, single divorcees had the lowest self-rated health.

## THE EMPTY NEST AND ITS REFILLING

An important event in a family is the launching of a child into adult life. Parents undergo adjustments as a result of the child's absence. College students usually think that their parents suffer from their absence. In fact, parents who live vicariously through their children might experience the **empty nest syndrome**, which includes a decline in marital satisfaction after children leave the home. For most parents, however, marital satisfaction does not decline after children have left home but rather increases during the years after child rearing (Fingerman & Baker, 2006). With their children gone, marital partners have time to pursue career interests and to spend with each other. One study revealed that the transition to an empty nest increased marital satisfaction and this increase was linked to an increase in the quality of time—but not the quantity of time—spent with partners (Gorchoff, John, & Nelson, 2008).

In today's uncertain economic climate, the refilling of the empty nest is becoming a common occurrence as adult children return home after several years of college, after graduating from college, or to save money after taking a full-time job (Merrill, 2009). Young adults also may move in with their parents after an unsuccessful career or a divorce. And some individuals don't leave home at all until their middle to late twenties because they cannot support themselves financially. Numerous labels have been applied to these young adults who return to their parents' homes to live, including "boomerang kids" and "B2B" (or Back-to-Bedroom) (Furman, 2005).

The middle generation has always provided support for the younger generation, even after the nest is bare. Through loans and monetary gifts for education, and through emotional support, the middle generation has helped the younger generation. Adult children appreciate the financial and emotional support their parents provide them at a time when they often feel considerable stress about their career, work, and lifestyle. And parents feel good that they can provide this support. A study of 40- to 60-year-old parents revealed that they provided financial, practical, and emotional support on average every few weeks to each of their children over 18 years of age (Fingerman & others, 2009).

However, as with most family living arrangements, there are both pluses and minuses when adult children return home. A common complaint voiced by both adult children and their parents is a loss of privacy. The adult children complain that their parents restrict their independence, cramp their sex lives, reduce their music listening, and treat them as children rather than adults. Parents often complain that their quiet home has become noisy, that they stay up late wondering when their adult children will come home, that meals are difficult to plan because of conflicting schedules, that their relationship as a married couple has been invaded, and that they have to shoulder too much responsibility for their adult children. In sum, when adult children return home to live, there is a disequilibrium in family life that requires considerable adaptation by parents and their adult children. To read about strategies that young adults and their parents can use to get along better, see *Connecting Development to Life*.

## SIBLING RELATIONSHIPS AND FRIENDSHIPS

Sibling relationships persist over the entire life span for most adults (Whiteman, McHale, & Soli, 2011). Eighty-five percent of today's adults have at least one living sibling. Sibling relationships in adulthood may be extremely close, apathetic, or highly rivalrous (Bedford, 2009). The majority of sibling relationships in adulthood are close (Cicirelli, 2009). Those siblings who are psychologically close to each other in adulthood tended to be that way in childhood. It is rare for sibling closeness to develop for the first time in adulthood (Dunn, 1984, 2007). One study revealed that adult siblings often provide practical and emotional support to each other

**empty nest syndrome** A decrease in marital satisfaction that occurs after children leave home, because parents derive considerable satisfaction from their children.

# connecting development to life

## Strategies for Parents and Their Young Adult Children

When adult children ask to return home to live, parents and their adult children should agree beforehand on the conditions and expectations. For example, they might discuss and agree on whether young adults will pay rent, wash their own clothes, cook their own meals, do any household chores, pay their phone bills, come and go as they please, be sexually active or drink alcohol at home, and so on. If these conditions aren't negotiated at the beginning, conflict often results because the expectations of parents and young adult children will likely be violated.

Parents need to treat young adult children more like adults than children and to let go of much of their parenting role. Parents should interact with young adult children not as dependent children who need to be closely monitored and protected but rather as adults who are capable of responsible, mature behavior. Adult children have the right to choose how much they sleep and eat, how they dress, whom they choose as friends and lovers, what career they pursue, and how they spend their money. However, if the young adult children act in ways that interfere with their parents' lifestyles, parents need to say so. The discussion should focus not on the young adult children's choices but on how their activities are unacceptable while living together in the same home.

Some parents don't let go of their young adult children when they should. They engage in "permaparenting," which can impede not only their adult children's movement toward independence and responsibility but also their own postparenting lives. "Helicopter parents" is another label that describes parents who hover too closely in their effort to ensure that their children succeed in college and

What are some strategies that can help parents and their young adult children get along better?  
©Fuse/Getty Images

adult life (Paul, 2003). Although well intentioned, this intrusiveness by parents can slow the process by which their children become responsible adults.

When they move back home, young adult children need to think about how they will need to change their behavior to make the living arrangement work. Elina Furman (2005) provides some good recommendations in *Boomerang Nation: How to Survive Living with Your Parents . . . the Second Time Around*. She recommends that when young adult children move back home they expect to make adjustments. And as recommended earlier, she urges young adults to sit down with their parents and negotiate the ground rules for living at home before they actually move back. Furman also

recommends that young adults set a deadline for how long they will live at home and then stay focused on their goals (whether they want to save enough money to pay off their debts, save enough to start a business or buy their own home, finish graduate school, and so on). Too often young adults spend the money they save by moving home on luxuries such as shopping binges, nights on the town, expensive clothes, and unnecessary travel, further delaying their ability to move out of their parents' home.

---

Children who leave college and return to live at home with their parents are on the cusp of young adulthood, a time called emerging adulthood. What characterizes individuals' identity development during this time?

---

(Voorpostel & Blieszner, 2008). Another study revealed that men who had poor sibling relationships in childhood were more likely to develop depression by age 50 than men who had more positive sibling relationships as children (Waldfinger, Vaillant, & Orav, 2007).

Friendships are as important in middle adulthood as they were in early adulthood (Blieszner & Roberto, 2012b). It takes time to develop intimate friendships, so friendships that have endured over the adult years are often deeper than those that are newly formed in middle adulthood.

## GRANDPARENTING

The increase in longevity is influencing the nature of grandparenting (Hayslip, Fruhauf, & Dolbin-MacNab, 2018; Huo & Fingerman, 2018). In 1900, only 4 percent of 10-year-old children had four living grandparents, but in 2000 that figure had risen to more than 40 percent.

### developmental connection

#### Family and Peers

Many siblings have mixed feelings about each other. Connect to "Socioemotional Development in Early Childhood."

And in 1990 only about 20 percent of people who were 30 years of age had living grandparents, a figure that is projected to increase to 80 percent in 2020 (Hagestad & Uhlenberg, 2007). Further increases in longevity are likely to support this trend in the future, although the current trend in delaying childbearing is likely to undermine it (Szinovacz, 2009).

Grandparents play important roles in the lives of many grandchildren (Bol & Kalmijn, 2016; Hayslip, Fruhauf, & Dolbin-MacNab, 2018; Huo & Fingerman, 2018; Zhou & others, 2016). Grandparents especially play important roles in grandchildren's lives when family crises such as divorce, death, illness, abandonment, or poverty occur (Dolbin-MacNab & Yancura, 2017). In many countries around the world, grandparents facilitate women's participation in the labor force by providing child care. Some estimates suggest that worldwide more than 160 million grandparents are raising grandchildren (Leinaweafer, 2014).

Many adults become grandparents for the first time during middle age. Researchers have consistently found that grandmothers have more contact with grandchildren than grandfathers do (Watson, Randolph, & Lyons, 2005). Perhaps women tend to define their role as grandmothers as part of their responsibility for maintaining ties between family members across generations. Men may have fewer expectations about the grandfather role and see it as more voluntary.

Most research on grandparents has focused on grandchildren as children or adolescents. A recent study focused on grandparents and their adult grandchildren (Huo & others, 2017). In this study, grandparents' contact with their adult grandchildren involved frequent listening, emotional support, and companionship. Also in this study, grandparents provided more frequent emotional support to their adult grandchildren when parents were having life problems and more frequent financial support when parents were unemployed.

**Grandparent Roles and Styles** What is the meaning of the grandparent role? Three prominent meanings are attached to being a grandparent (Neugarten & Weinstein, 1964). For some older adults, being a grandparent brings a sense of biological reward and continuity. For others, being a grandparent is a source of emotional self-fulfillment, generating feelings of companionship and satisfaction that may have been missing in earlier adult-child relationships. And for yet others, being a grandparent is a remote role. One study revealed that grandparenting can provide a sense of purpose and a feeling of being valued during middle and late adulthood when generative needs are strong (Thiele & Whelan, 2008).

The grandparent role may have different functions in different families, in different ethnic groups and cultures, and in different situations (Hayslip, Fruhauf, & Dolbin-MacNab, 2018; Watson, Randolph, & Lyons, 2005). For example, in one study of White, African American, and Mexican American grandparents and grandchildren, the Mexican American grandparents saw their grandchildren most frequently, provided the most support for the grandchildren and their parents, and had the most satisfying relationships with their grandchildren (Bengtson, 1985). And in a study of three generations of families in Chicago, grandmothers had closer relationships with their children and grandchildren and gave more personal advice than grandfathers did (Hagestad, 1985).

The diversity of grandparenting also was apparent in an early investigation of how grandparents interacted with their grandchildren (Neugarten & Weinstein, 1964). Three styles were dominant—formal, fun-seeking, and distant. In the formal style, the grandparent performed what was considered to be a proper and prescribed role. These grandparents showed a strong interest in their grandchildren but were careful not to give child-rearing advice. In the fun-seeking style, the grandparent was informal and playful. Grandchildren were a source of leisure activity; mutual satisfaction was emphasized. A substantial portion of grandparents were distant figures. In the distant-figure style, the grandparent was benevolent but interaction was infrequent. Grandparents who were over the age of 65 were more likely to display a formal style of interaction; those under 65 were more likely to display a fun-seeking style. Because the grandparent role links three generations—grandparents, parents, and grandchildren—the grandparent role is often mediated by parents at least until grandchildren become adults (Szinovacz, 2009).

**The Changing Profile of Grandparents** In 2014, 10 percent (7.4 million) of children in the United States lived with at least one grandparent,

*What are some grandparents' roles and styles?*  
©JGI/Jamie Grill/Getty Images

a dramatic increase since 1981 when 4.7 million children were living with at least one grandparent (U.S. Census Bureau, 2015). Divorce, adolescent pregnancies, and drug use by parents are the main reasons that grandparents are thrust back into the “parenting” role they thought they had shed. One study revealed that grandparent involvement was linked with better adjustment in single-parent and stepparent families than in two-parent biological families (Attar-Schwartz & others, 2009).

Less than 20 percent of grandparents whose grandchildren move in with them are 65 years old or older. Almost half of the grandchildren who move in with grandparents are raised by a single grandmother. These families are mainly African American (53 percent). When both grandparents are raising grandchildren, the families are overwhelmingly non-Latino White.

A majority of the grandparents living with their children contribute to the family income and provide child care while parents worked. Only about 10 percent of the grandparents who move in with their children and grandchildren are in poverty. Almost half of the grandparents who move in with their children are immigrants. Partly because women live longer than men, more grandmothers than grandfathers live with their children. About 70 percent of the grandparents who move in with their children are grandmothers.

Grandparents who are full-time caregivers for grandchildren are at elevated risk for health problems, depression, and stress (Hayslip, Fruhauf, & Dolbin-MacNab, 2018; Silverstein, 2009). One research review concluded that grandparents raising grandchildren are especially at risk for developing depression (Hadfield, 2014). Caring for grandchildren is linked with these problems in part because full-time grandparent caregivers are often characterized by low-income, minority status, and by not being married (Minkler & Fuller-Thompson, 2005). Grandparents who are part-time caregivers are less likely to have the negative health status that full-time grandparent caregivers have. In a study of part-time grandparent caregivers, few negative effects on grandparents were found (Hughes & others, 2007).

In some cases, divorce may increase children’s contact with grandparents, as when grandparents assume a stronger caregiving role; in others, a custodial parent may try to restrict grandparents’ time with children. One study revealed that when children’s relationship with their father deteriorated after a divorce, their relationships with their paternal grandparents also were distant, negative, or nonexistent (Ahrons, 2007).

As divorce and remarriage have become more common, a special concern of grandparents is visitation privileges with their grandchildren (Kivnik & Sinclair, 2007). In the last two decades, more states have passed laws giving grandparents the right to petition a court for visitation privileges with their grandchildren, even if a parent objects. Whether such forced visitation rights for grandparents are in the child’s best interest is still being debated.

## INTERGENERATIONAL RELATIONSHIPS

Family is important to most people (Pasco Fearon & Roisman, 2017; Sechrist & Fingerman, 2018). When 21,000 adults aged 40 to 79 in 21 countries were asked, “When you think of who you are, you think mainly of \_\_\_\_\_,” 63 percent said “family,” 9 percent said “religion,” and 8 percent said “work” (HSBC Insurance, 2007). In this study, in all 21 countries, middle-aged and older adults expressed a strong feeling of responsibility between generations in their family, with the strongest intergenerational ties indicated in Saudi Arabia, India, and Turkey. More than 80 percent of the middle-aged and older adults reported that adults have a duty to care for their parents (and parents-in-law) in time of need later in life.

Adults in midlife play important roles in the lives of the young and the old (Birditt & others, 2016; Fingerman, Sechrist, & Birditt, 2013; Fingerman & others, 2014, 2018; Luong, Rauers, & Fingerman, 2015; Polenick, Birditt, & Zarit, 2018). Middle-aged adults share their experience and transmit values to the younger generation. They may be launching children and experiencing the empty nest, adjusting to having grown children return home, or becoming grandparents. They also may be giving or receiving financial assistance, caring for a widowed or sick parent, or adapting to being the oldest generation after both parents have died.

Middle-aged and older adults around the world show a strong sense of family responsibility. A study of middle-aged and older adults in 21 countries revealed the strongest intergenerational ties in Saudi Arabia.

©Reza/National Geographic/Getty Images

Middle-aged adults have been described as the “sandwich,” “squeezed,” or “overload” generation because of the responsibilities they have for their adolescent and young adult children as well as their aging parents (Etaugh & Bridges, 2010; Pudrovska, 2009). However, an alternative view is that in the United States, a “sandwich” generation, in which the middle generation cares for both grown children and aging parents simultaneously, occurs less often than a “pivot” generation, in which the middle generation alternates attention between the demands of grown children and aging parents (Fingerman, Sechrist, & Birditt, 2013; Fingerman & others, 2018; Luong, Rauers, & Fingerman, 2015).

Many middle-aged adults experience considerable stress when their parents become very ill and die. One survey found that when adults enter midlife, 41 percent have both parents alive, but that 77 percent leave midlife with no parents alive (Bumpass & Aquilino, 1994). By middle age, more than 40 percent of adult children (most of them daughters) provide care for aging parents or parents-in-law (Blieszner & Roberto, 2012a; National Alliance for Caregiving, 2009). However, two studies revealed that middle-aged parents are more likely to provide support to their grown children than to their parents (Fingerman & others, 2011a, 2012). When middle-aged adults have a parent with a disability, their support for that parent increases (Fingerman & others, 2011b). This support might involve locating a nursing home and monitoring its quality, procuring medical services, arranging public service assistance, and handling finances. In some cases, adult children provide direct assistance with daily living, including such activities as eating, bathing, and dressing. Even less severely impaired older adults may need help with shopping, housework, transportation, home maintenance, and bill paying.

Some researchers have found that relationships between aging parents and their children are usually characterized by ambivalence (Fingerman, Sechrist, & Birditt, 2013; Luong, Rauers, & Fingerman, 2015; Pitzer, Fingerman, & Lefkowitz, 2014; Sechrist & Fingerman, 2018). Perceptions include love, reciprocal help, and shared values on the positive side and isolation, family conflicts and problems, abuse, neglect, and caregiver stress on the negative side. One study found that middle-aged adults positively supported family responsibility to emerging adult children but were more ambivalent about providing care for aging parents, viewing it as both a joy and a burden (Igarashi & others, 2013). However, a study in the Netherlands revealed that affection and support, reflecting solidarity, were more prevalent than ambivalence in intergenerational relationships (Hogerbrugge & Komter, 2012).

With each new generation, personality characteristics, attitudes, and values are replicated or changed (Sechrist & Fingerman, 2018). As older family members die, their biological, intellectual, emotional, and personal legacies are carried on in the next generation. Their children become the oldest generation and their grandchildren the second generation. As adult children become middle-aged, they often develop more positive perceptions of their parents (Field, 1999). Both similarity and dissimilarity across generations are found. For example, similarity between parents and an adult child is most noticeable in religion and politics, least in gender roles, lifestyle, and work orientation.

There has been a significant increase in research on intergenerational relationships in recent years (Andreas & others, 2018; Claydon & others, 2018; Niu, Liu, & Wang, 2018; Woods-Jaeger & others, 2018; Wu & others, 2018). The following studies provide further evidence of the importance of intergenerational relationships in development:

- The motivation of adult children to provide social support to their older parents was linked with earlier family experiences (Silverstein & others, 2002). Children who spent more time in shared activities with their parents and received more financial support from them earlier in their lives provided more support to their parents as they became older.
- Children of divorced parents were disproportionately likely to end their own marriage than were children from intact, never-divorced families, although the transmission of divorce across generations has declined in recent years (Wolfinger, 2011).
- Parent and offspring marital disruptions were linked, with each parental disruption associated with a 16 percent increase in the number of offspring disruptions (Amato &

*What is the nature of intergenerational relationships?*

©Ron Levine/Photolibrary/Getty Images

Patterson, 2017). Marital conflict in intact families also was related to more marital disruptions in offspring.

- When a grown child suffered problems it decreased parents' well-being (Suitor & others, 2017). When more grown children suffered problems, parental well-being decreased further.
- Older adult fathers had elevated depressive symptoms when they reported having more negative relationships with their middle-aged children (Polenick & others, 2017). Also in this study, the association was worse for older adult fathers and their middle-aged daughters. The fathers who were in better health had better relationships with their daughters.
- In an intergenerational study of African Americans, grown children who had a better relationship with their biological father (but not social father) were more involved as fathers with their own children (Brown, Kogan, & Kim, 2017).
- Safe, stable, and supportive/trusting relationships with intimate partners and between mothers and children were linked to breaking the intergenerational cycle of abuse in families (Jaffee & others, 2013).
- In a recent Chinese study, sons were more likely to receive financial support and helping/caring support from elderly parents (Chen & Jordan, 2018). Also in this study, sons were more likely to give financial support to elderly parents while daughters were more likely to give them helping/caring support (Chen & Jordan, 2018).

Gender differences also characterize intergenerational relationships (Luong, Rauers, & Fingerman, 2015). Women play an especially important role in maintaining family relationships across generations. Women's relationships across generations are typically closer than other family bonds (Merrill, 2009). In one study, mothers and their daughters had much closer relationships during their adult years than mothers and sons, fathers and daughters, and fathers and sons (Rossi, 1989). Also in this study, married men were more involved with their wives' kin than with their own. One study revealed that mothers' intergenerational ties were more influential for grandparent-grandchild relationships than fathers' (Monserud, 2008).

When adults immigrate into another country, intergenerational stress may increase (Lin & others, 2014). In the last several decades, increasing numbers of Mexicans have immigrated into the United States, and their numbers are expected to increase. The pattern of immigration usually involves separation from the extended family (Parra-Cardona & others, 2006). It may also involve separation of immediate family members, with the husband coming first and then later bringing his wife and children. Those who were initially isolated, especially the wife, experience considerable stress due to relocation and the absence of family and friends. Within several years, a social network is usually established in the ethnic neighborhood.

As soon as some stability in their lives is achieved, Mexican families may sponsor the immigration of extended family members, such as a maternal or paternal sister or mother who provides child care and enables the mother to go to work. In some cases, the older generation remains behind and joins their grown children in old age. The accessibility of Mexico facilitates visits to and from the village for vacations or at a time of crisis, such as when an adolescent runs away from home.

The discrepancies between acculturation levels can give rise to conflicting expectations within Mexican American families (Sarkisian, Gerena, & Gerstel, 2006; Simpkins, Vest, & Price, 2011). The immigrant parents' model of child rearing may be out of phase with the dominant culture's model, which may cause reverberations through the family's generations, as discussed in earlier chapters. For example, parents and grandparents may be especially resistant to the demands for autonomy and dating made by adolescent daughters (Wilkinson-Lee & others, 2006). And in recent years an increasing number of female youth have left their Mexican American homes to further their education, an event that is often stressful for families with strong ties to Mexican values.

Karen Fingerman has conducted research on intergenerational relations and development in midlife. To read about her work, see the *Connecting with Careers* profile.

What are three levels of acculturation that characterize many Mexican American families?

Erikson's eighth and final stage of development—integrity versus despair—occurs in late adulthood. In this stage, individuals engage in a life review. Being active is linked with life satisfaction in late adulthood. Older adults become more selective about their social networks and choose to spend more time with emotionally rewarding relationships and less time with peripheral relationships. Older adults also experience more positive emotions and fewer negative emotions than younger adults. The personality traits of conscientiousness and agreeableness also increase in late adulthood. Because of losses (declines in physical or cognitive skills, for example), older adults often have to use accommodative strategies to reach their goals.

## Socioemotional Development in Middle Adulthood

### 1 Personality Theories and Adult Development

Stages of Adulthood

**LG1** Describe personality theories and socioemotional development in middle adulthood.

- Erikson says that the seventh stage of the human life span, generativity versus stagnation, occurs in middle adulthood. Four types of generativity are biological, parental, work, and cultural.
- In Levinson's theory, developmental tasks must be mastered at different points in development, and changes in middle age focus on four conflicts: being young versus being old, being destructive versus being constructive, being masculine versus being feminine, and being attached to others versus being separated from them. Levinson asserted that a majority of Americans, especially men, experience a midlife crisis. Research, however, indicates that midlife crises are not pervasive. There is considerable individual variation in development during middle adulthood.
- According to the early version of the life-events approach, life events produce taxing circumstances that create stress. In the contemporary version of the life-events approach, how life events influence the individual's development depends not only on the life event but also on mediating factors, adaptation to the event, the life-stage context, and the sociohistorical context.
- Researchers have found that young and middle-aged adults experience more stressful days and more multiple stressors than do older adults. On average, a sense of personal control decreases as adults become older—however, some aspects of personal control increase. Women and men differ in the way they experience and respond to stressors. Women are more likely to respond to stress in a tend-and-befriend manner, men in a fight-or-flight manner.
- Neugarten argues that the social environment of a particular cohort can alter its social clock—the timetable on which individuals are expected to accomplish life's tasks. Critics say that the adult stage theories are male-biased because they place too much emphasis on achievement and careers and do not adequately address women's concerns about relationships. Midlife is a heterogeneous period for women, as it is for men. For some women, midlife is the prime of their lives. Many cultures do not have a clear concept of middle age. In many nonindustrialized societies, a woman's status improves in middle age.

### 2 Stability and Change

Longitudinal Studies

**LG2** Discuss stability and change in development during middle adulthood, as reflected in longitudinal studies.

- In Costa and McCrae's Baltimore Study, the Big Five personality factors—openness to experience, conscientiousness, extraversion, agreeableness, and neuroticism—showed considerable stability. However, researchers recently have found that the greatest change in personality occurs in early adulthood, with positive aspects of the factors peaking in middle age. The Big Five factors are linked to important aspects of a person's life, such as health and work.
- In the Berkeley Longitudinal Studies, extremes in the stability-change argument were not supported. The most stable characteristics were intellectual orientation, self-confidence, and openness to new experiences. The characteristics that changed the most were nurturance, hostility, and self-control.
- Helson's Mills College Study of women distinguished family-oriented and career-oriented women, and those who followed neither path. In their early forties, women experienced many of the concerns that Levinson described for men. However, rather than a midlife crisis, women experienced midlife consciousness.

- George Vaillant's research revealed links between a number of characteristics at age 50 and health and well-being at 75 to 80 years of age.
- The cumulative personality model states that with time and age personality becomes more stable. Changes in personality traits occur more in early adulthood than middle and late adulthood, but a number of aspects of personality do continue to change after early adulthood. Change in personality traits across adulthood occurs in a positive direction, reflecting social maturity. At the individual level, changes in personality are often linked to life experiences related to a particular developmental period. Some people change more than others.

### 3 Close Relationships

Love and Marriage  
at Midlife

The Empty Nest and  
Its Refilling

Sibling Relationships and  
Friendships

Grandparenting

Intergenerational  
Relationships

**LG3**

Identify some important aspects of close relationships in middle adulthood.

- Affectionate love increases in midlife, especially in marriages that have endured for many years. A majority of middle-aged adults who are married say that their marriage is very good or excellent. Researchers recently have found that the perils of divorce in midlife can be fewer and less intense than those for divorcing young adults.
- Rather than decreasing marital satisfaction as once thought, the empty nest increases it for most parents. Following an unsuccessful career or a divorce, an increasing number of young adults are returning home to live with their parents. Some young adults do not leave home until their middle to late twenties because they are unable to support themselves financially.
- Sibling relationships continue throughout life. Some are close; others are distant. Friendships continue to be important in middle age.
- There are different grandparent roles and styles. Grandmothers spend more time with grandchildren than grandfathers do, and the grandmother role involves greater expectations for maintaining ties across generations than the grandfather role. The profile of grandparents is changing because of factors such as divorce and remarriage. An increasing number of U.S. grandchildren live with their grandparents.
- Family members usually maintain contact across generations. Mothers and daughters have the closest relationships. The middle-aged generation, which has been called the "sandwich" or "squeezed" generation, plays an important role in linking generations.

## Late Adulthood

The rhythm and meaning of human development eventually wend their way to late adulthood, when each of us stands alone at the heart of the earth and suddenly it is evening. We shed the leaves of youth and are stripped by the winds of time down to the truth. We learn that life is lived forward but understood backward. We trace the connection between the end and the beginning of life and try to figure out what this whole show is about before it is out. Ultimately, we come to know that we are what survives of us. This section contains three chapters: “Physical Development in Late Adulthood,” “Cognitive Development in Late Adulthood,” and “Socioemotional Development in Late Adulthood.”

# PHYSICAL DEVELOPMENT IN LATE ADULTHOOD

## chapter outline

### ① Longevity

**Learning Goal 1** Characterize longevity and discuss the biological theories of aging

Life Expectancy and Life Span

The Young-Old and the Oldest-Old

Biological Theories of Aging

### ② The Course of Physical Development in Late Adulthood

**Learning Goal 2** Describe how a person's brain and body change in late adulthood

The Aging Brain

Sleep

Physical Appearance and Movement

Sensory Development

The Circulatory and Respiratory Systems

Sexuality

### ③ Health

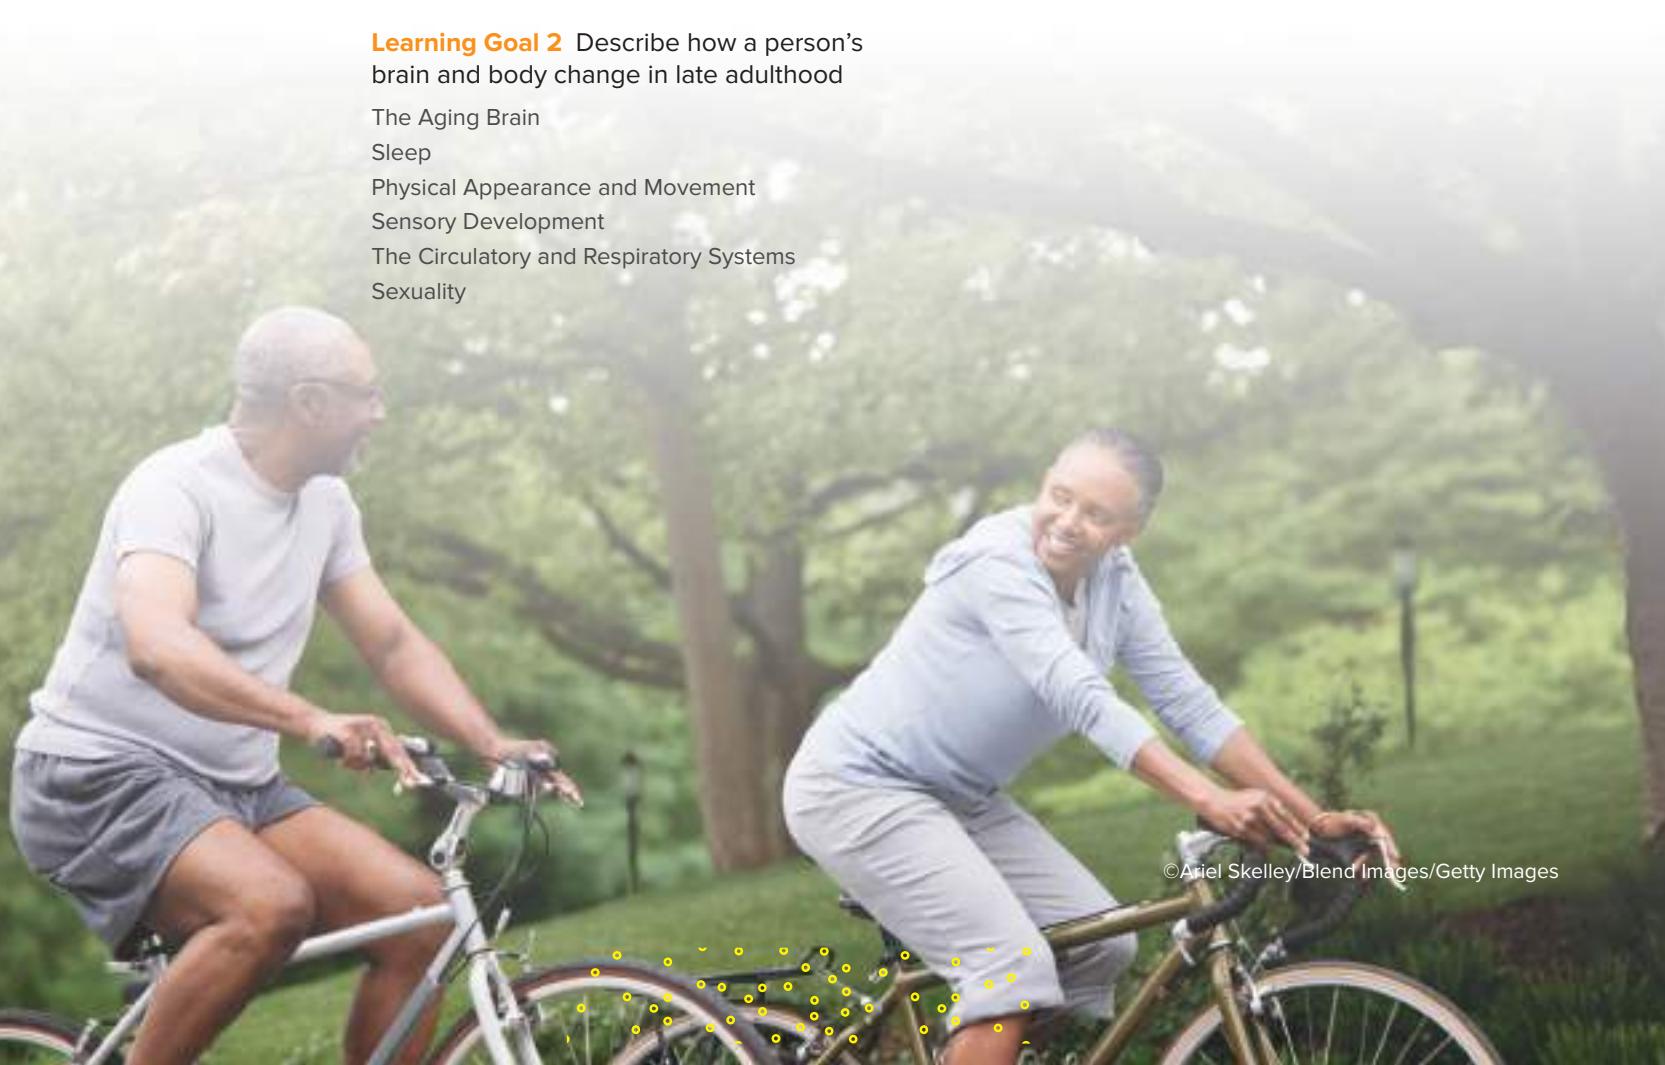

**Learning Goal 3** Identify health problems in older adults and describe how they can be treated

Health Problems

Substance Use and Abuse

Exercise, Nutrition, and Weight

Health Treatment

**J**onathan Swift said, “No wise man ever wished to be younger.” Without a doubt, a 70-year-old body does not work as well as it once did. It is also true that an individual’s fear of aging is often greater than need be. As more individuals live to a ripe *and* active old age, our image of aging is changing. Although on average a 75-year-old’s joints should be stiffening, people can practice not to be average. For example, a 75-year-old man might choose to train for and run a marathon; an 80-year-old woman whose capacity for work is undiminished might choose to make and sell children’s toys.

May Segal engages in her exercise routine on her 100th birthday at the Duke University Health and Fitness Center.  
©Jill Knight/The News & Observer/AP Images

Consider Mary “May” Segal, who was diagnosed with cardiovascular problems about the time she retired at the age of 65. Her heart complications spurred her to begin an exercise program that involved climbing the steps at Duke University’s football stadium in Durham, North Carolina. May turned 100 years of age in 2013 and maintained a regular exercise regimen for more than 35 years. When May was 78, she began exercising at the newly opened Duke University Health and Fitness Center. At 100, she was still going to the Center regularly, starting just after 9 a.m. May’s exercise regimen included a swim, four laps walking around a track, and a 30-minute workout on a NuStep machine that combined leg exercise akin to climbing stairs with arm exercise similar to cross-country skiing. May’s exercise speed was slower than it had been when she was younger, and she was using a walker for her four laps around the track. In addition, she reduced her workout regimen to three days per week.

May’s motivation, resilience, and persistence is evident in her response to an unexpected injury. When she was 94 she fell and broke her hip, which for elderly adults can be a difficult setback with a prolonged recovery period. Her doctor told her she would never walk again, but May recovered and resumed her regular exercise program. After living a very long and fulfilling life, May passed away in December 2015.

## topical connections *looking back*

As more individuals are living healthier lives and medical discoveries are slowing down the aging process, middle age appears to be starting later and lasting longer. Increasingly, early middle age (40–54) is distinguished from late middle age (55–65). However, middle age is a time of declining physical skills—such as loss of height, impaired vision and hearing, and reduced cardiovascular functioning. Sleep also becomes more problematic. Sexual changes occur as women enter menopause, many middle-aged men begin to experience erectile dysfunction, and couples engage less frequently in sexual intercourse.

# preview

The story of May Segal's physical development and well-being raises some truly fascinating questions about life-span development, which we will explore in this chapter. They include: Why do we age, and what, if anything, can we do to slow down the process? How long can we live? What chance do we have of living to be 100? How does the body change in old age? Can certain eating habits and exercise patterns help us live longer? How can we enhance older adults' quality of life?

## 1 Longevity

LG1

Characterize longevity and discuss the biological theories of aging.

Life Expectancy and Life Span

The Young-Old and the Oldest-Old

Biological Theories of Aging

In his eighties, Nobel-winning chemist Linus Pauling argued that vitamin C slows the aging process. Aging researcher Roy Walford fasted two days a week because he believed calorie restriction slowed the aging process. What do we really know about longevity?

### LIFE EXPECTANCY AND LIFE SPAN

We are no longer a youthful society. The proportion of individuals at different ages has become increasingly similar. Since the beginning of recorded history, **life span**, the maximum number of years an individual can live, has remained at approximately 120 to 125 years of age. But since 1900, improvements in medicine, nutrition, exercise, and lifestyle have increased our life expectancy by an average of 30 years. Keep in mind that it is not just improvements in the health and well-being of adults that have contributed to increased longevity but also the substantial reduction in infant deaths in recent decades.

Recall that **life expectancy** is the number of years that the average person born in a particular year will probably live. The average life expectancy of individuals born in 2016 in the United States was 79 years (U.S. Census Bureau, 2017). Sixty-five-year-olds in the United States today can expect to live an average of 19.5 more years (20.6 for females, 18.4 for males) (U.S. Department of Health and Human Services, 2017). Older adults who are 100 years of age can only expect to live an average of 2.3 years longer (U.S. Census Bureau, 2011).

**Life Expectancy** How does the United States fare in life expectancy, compared with other countries around the world? We do considerably better than some and somewhat worse than others. In 2015, Monaco had the highest estimated life expectancy at birth (90 years), followed by Japan, Singapore, and Macau (a region of China near Hong Kong) (85 years) (Central Intelligence Agency, 2015). Of 224 countries, the United States ranked 43rd at 79 years. The lowest estimated life expectancy in 2015 occurred in the African countries of Chad and Guinea-Bissau (50) and Swaziland and Afghanistan (51 years). Differences in life expectancies across countries are due to such factors as health conditions and medical care throughout the life span.

In a recent analysis, projections of life expectancy in 2030 were made for 35 developed countries (Kontis & others, 2017). It was predicted that life expectancy in the United States would increase to 83.3 years for women and 79.5 years for men by 2030. However, the United States, although expected to increase in life expectancy, had one of the lowest growth rates in life expectancy for all the countries in the study. South Korea is projected to have the highest life expectancy in 2030, with South Korean women predicted to have an average life expectancy of 90.8, the first nation to break the 90-year life expectancy barrier. So why the lower growth in life expectancy for the United States and the very high growth for South Korea? The United States has the highest child and maternal mortality, homicide rate, and body-mass index of high-income countries in the world. In South Korea, delayed onset of chronic diseases is occurring and children's nutrition is improving. South Korea also has a low rate of obesity, and blood pressure is not as high as it is in most countries.

To me old age is always  
fifteen years older than I am.

—BERNARD BARUCH

*American Statesman, 20th Century*

Each of us stands alone at  
the heart of the earth,  
pierced through by a ray of  
sunshine: And suddenly it is  
evening.

—SALVATORE QUASIMODO

*Italian Poet, 20th Century*

**life span** The maximum number of years an individual can live. The life span of human beings is about 120 to 125 years of age.

**life expectancy** The number of years that will probably be lived by the average person born in a particular year.

(a)

(b)

(C)

(a) People in Monaco, a very wealthy country with virtually no poverty and superb health care, have the highest life expectancy in the world (90 years); (b) Life expectancy in Russia is only 66 years of age, likely due to high rates of alcohol consumption and tobacco use; and (c) Haiti, a country with high rates of poverty where many newborns have a low birth weight, has a life expectancy of 63.

(a) ©Christophe Ena/AP Images; (b) ©Anatoly Semekhin/ITAR-TASS/Newscom; (c) ©Chip Somodevilla/Getty Images

Life expectancy also differs for various ethnic groups within the United States and for men and women. For example, in 2014 the life expectancy of African Americans (73.1) in the United States was 7.2 years lower than the life expectancy for Latinos (80.3) and 5.7 years lower than for non-Latino Whites (78.8) (U.S. Department of Health and Human Services, 2017). Latino women had a life expectancy of 82.9 and non-Latino White women had a life expectancy of 81.1, followed by African American women (78.1), non-Latino White men (76.5 years), and African American men (72 years) (U.S. Department of Health and Human Services, 2017). The differences in life expectancies for various ethnicities have increased in recent years, likely because of the powerful influence of education, and some experts argue that closing the gap entirely may not be possible (Olshansky & others, 2012).

In 2014, the overall life expectancy for women was 81.4 years of age, and for men it was 76.7 years of age (U.S. Department of Health and Human Services, 2017). Beginning in their mid-thirties, women outnumber men; this gap widens during the remainder of the adult years. By the time adults are 75 years of age, more than 61 percent of the population is female; for those 85 and over, the figure is almost 70 percent female. Why can women expect to live longer than men? Social factors such as health attitudes, habits, lifestyles, and occupation are probably important. Men are more likely than women to die from most of the leading causes of death in the United States, including cancer of the respiratory system, motor vehicle accidents, cirrhosis of the liver, emphysema, and heart disease (Pedersen & others, 2016). These causes of death are associated with lifestyle. For example, the sex difference in deaths due to lung cancer and emphysema occurs because men are heavier smokers than women. However, women are more likely than men to die from some disorders such as Alzheimer disease and some aspects of cardiovascular disease, such as hypertension-related problems (Ostan & others, 2016).

The sex difference in longevity also is influenced by biological factors (Beltran-Sanchez, Finch, & Crimmins, 2015). In virtually all species, females outlive males. Women have more resistance to infections and degenerative diseases (Pan & Chang, 2012). For example, the female's estrogen production helps to protect her from arteriosclerosis (hardening of the arteries) (Valera & others, 2015). And the additional X chromosome that women carry in comparison with men may be associated with the production of more antibodies to fight off disease. The sex difference in mortality is still present but less pronounced than in the past. In 1979, the sex difference in longevity favored women by 7.8 years, but in 2013 the difference was down to 4.8 years (U.S. Department of Health and Human Services, 2015).

Among various groups, the longest average longevity in the United States belongs to Seventh Day Adventists, who have a life expectancy of 88 years. One reason for their longevity is that their religious practices include positive lifestyle choices such as a vegetarian diet.

What about your own life expectancy? What is the likelihood that you will live to be 100? To evaluate this possibility, see Figure 1.

**Centenarians** In developed countries, the number of centenarians (individuals 100 years and older) is increasing at a rate of approximately 7 percent each year (Perls, 2007). In the United States, there were only 15,000 centenarians in 1980, but that number rose to 50,000 in 2000 and to 72,000 in 2014 (Xu, 2016). The number of U.S. centenarians is projected to reach 600,000 by 2050 (U.S. Census Bureau, 2011). The United States has the most centenarians, followed by Japan, China, and England/Wales (Hall, 2008). It is estimated that there are about 60 to 70 supercentenarians (individuals 110 years or older) in the United States and about 300 to 450 worldwide (Perls, 2007). In a recent study of U.S. and Japanese centenarians, in both countries, health resources (better cognitive function, fewer hearing problems, and positive activities in daily living) were linked to a higher level of well-being (Nakagawa & others, 2017).

Three major studies of centenarians are the New England Centenarian Study, the Georgia Centenarian Study, and the Chinese Longitudinal Healthy Longevity Survey. The New England Centenarian Study (NECS) began in 1994 under the direction of Thomas Perls and his colleagues (Fagan & others, 2017; Perls, 2007, 2009; Sebastiani & Perls, 2012; Sebastiani & others, 2012, 2013, 2017; Terry & others, 2008). Many people expect that "the older you get, the sicker you get." However, according to the NECS, this is not true for a majority of centenarians. The researchers have found that chronic high-mortality diseases are markedly delayed for many years in centenarians, with many not experiencing disability until near the end of their lives (Sebastiani & Perls, 2012). A NECS study of centenarians from 100 to 119 years of age found that the older the age group (110 to 119—referred to as *supercentenarians*)—compared with 100 to 104,

## Life Expectancy

Decide how each item applies to you and add or subtract the appropriate number of years from your basic life expectancy.

### 1. Family history

- Add five years if two or more of your grandparents lived to 80 or beyond.
- Subtract four years if any parent, grandparent, sister, or brother died of a heart attack or stroke before 50.
- Subtract two years if anyone died from these diseases before 60.
- Subtract three years for each case of diabetes, thyroid disorder, breast cancer, cancer of the digestive system, asthma, or chronic bronchitis among parents or grandparents.

### 2. Marital status

- If you are married, add four years.
- If you are over 25 and not married, subtract one year for every unmarried decade.

### 3. Economic status

- Add two years if your family income is over \$60,000 per year.
- Subtract three years if you have been poor for the greater part of your life.

### 4. Physique

- Subtract one year for every 10 pounds you are overweight.
- For each inch your girth measurement exceeds your chest measurement deduct two years.
- Add three years if you are over 40 and not overweight.

### 5. Exercise

- Add three years if you exercise regularly and moderately (jogging three times a week).
- Add five years if you exercise regularly and vigorously (long-distance running three times a week).
- Subtract three years if your job is sedentary.
- Add three years if your job is active.

### 6. Alcohol

- Add two years if you are a light drinker (one to three drinks a day).
- Subtract five to ten years if you are a heavy drinker (more than four drinks per day).
- Subtract one year if you are a teetotaler.

### 7. Smoking

- Subtract eight years if you smoke two or more packs of cigarettes per day.
- Subtract two years if you smoke one to two packs per day.
- Subtract two years if you smoke less than one pack.
- Subtract two years if you regularly smoke a pipe or cigars.

### 8. Disposition

- Add two years if you are a reasoned, practical person.
- Subtract two years if you are aggressive, intense, and competitive.
- Add one to five years if you are basically happy and content with life.
- Subtract one to five years if you are often unhappy, worried, and often feel guilty.

### 9. Education

- Subtract two years if you have less than a high school education.
- Add one year if you attended four years of school beyond high school.
- Add three years if you attended five or more years beyond high school.

### 10. Environment

- Add four years if you have lived most of your life in a rural environment.
- Subtract two years if you have lived most of your life in an urban environment.

### 11. Sleep

- Subtract five years if you sleep more than nine hours a day.

### 12. Temperature

- Add two years if your home's thermostat is set at no more than 68° F.

### 13. Health care

- Add three years if you have regular medical checkups and regular dental care.
- Subtract two years if you are frequently ill.

### Your Life Expectancy Total

## FIGURE 1

**CAN YOU LIVE TO BE 100?** This test gives you a rough guide for predicting your longevity. The basic life expectancy for men is 75 years, and for women it is 81. Write down your basic life expectancy. If you are in your fifties or sixties, you should add ten years to the basic figure because you have already proved yourself to be a durable individual. If you are over age 60 and active, you can add another two years.

for example), the later the onset of diseases such as cancer and cardiovascular disease, as well as functional decline (Andersen & others, 2012). Perls refers to this process of staving off high-mortality chronic diseases until much later ages than usual as the *compression of morbidity*.

Among the factors in the NECS that are associated with living to be 100 are longevity genes and the ability to cope effectively with stress. The researchers also have discovered a strong genetic component of living to be 100 that consists of many genetic links that each have modest effects but as a group can have a strong influence (Sebastiani & Perls, 2012). For example, a meta-analysis of five studies in the United States, Europe, and Japan concluded that when their influence is combined, approximately 130 genes "do a relatively good job" of differentiating centenarians from non-centenarians (Sebastiani & others, 2013). These genes play roles in Alzheimer disease, diabetes, cardiovascular disease, cancer, and various biological processes. Other characteristics of centenarians in the New England Centenarian Study include the following: few of the centenarians are obese, habitual smoking is rare, and only a small percentage (less than 15 percent) have had significant changes in their thinking skills (disproving the belief that most centenarians likely would develop Alzheimer disease).

In addition to the New England Centenarian Study, another major ongoing study is the Georgia Centenarian Study conducted by Leonard Poon and his colleagues (Baek & others, 2017;

Three participants in the New England Centenarian Study: (top) Agnes Fenton of Englewood, New Jersey, celebrated her 110th birthday in 2015. She still cooked her own meals and said that believing in God was a key factor in her longevity. (middle) Louis Charpentier, from the Boston area, was 104 and his main hobby was carving wooden figures in his basement shop. Louis said his memory was still very good. (bottom) Edythe Kirchmaier, from the New York City area, was Facebook's oldest user at 105 years of age. In July 2014 Edythe had more than 51,000 followers on Facebook. She volunteered every week at her favorite charity, still drove her car, and used the Internet to look up information and facts.

(Top) ©Carmine Galasso/The Record/MCT/Newscom;  
(middle) Courtesy of the New England Centenarian Study,  
Boston University; (bottom) ©Isaac Hernandez

Lee, Martin, & Poon, 2017; Lee & others, 2018; Lockhart & others, 2017; Nakagawa & others, 2018; Neltner & others, 2016; Ng & others, 2017; Poon & others, 2010, 2012; Toyoshima & others, 2018; Yang & others, 2018). In a review, Poon and his colleagues (2010) concluded that social dynamics involving life events (experiencing a higher number of negative life events is linked to lower self-rated health), personality (conscientiousness is positively associated with higher levels of physical and mental health), cognition (cognitive measures are better predictors of mental health than physical health), and socioeconomic resources and support systems (social, economic, and personal resources are related to mental and physical health) contribute to the health and quality of life of older adults, including centenarians. In another study, U.S. centenarians were more likely to talk about events related to marriage and children, while Japanese centenarians were more likely to describe historical events, death/grief, and work/retirement events (da Rosa & others, 2015). And in a recent study of U.S. and Japanese centenarians, in both countries, health resources (better cognitive function, fewer hearing problems, and positive activities in daily living) were linked to a higher level of well-being (Nakagawa & others, 2018).

Yet another major study is the Chinese Longitudinal Healthy Longevity Survey, which includes older adults, some of whom are centenarians (An & Liu, 2016; Fong & Feng, 2018; Li & Otani, 2018; Liu & others, 2018; Wang, J., & others, 2018; Zeng & others, 2016; Zhong, Chen, & Conwell, 2016; Zhong & others, 2017; Zhou, Wang, & Fang, 2018). In one investigation involving this sample, Chinese centenarians showed better coping and adjustment (greater personal tenacity, optimism, coping with negative moods, secure relationships, and personal control) than their Chinese counterparts in their nineties, eighties, or seventies (Zeng & Shen, 2010). In this study, 94- to 98-year-olds with better resilience had a 43 percent higher likelihood of becoming a centenarian than their same-aged counterparts who were less resilient. In a recent Chinese Longitudinal Healthy Longevity survey, a higher level of education was linked to greater longevity (Luo, Zhang, & Gu, 2015). And in another recent study with this sample, severe loneliness at prior assessment points predicted poorer cognitive function in subsequent assessments (Zhong & others, 2017).

How do centenarians view their lives? What are their opinions about why they have been able to live so long?

- Elza Wynn concludes that he has been able to live so long because he has made up his mind to do so. He says he was thinking about dying when he was 77, but decided to wait a while (Segerberg, 1982).
- Ruth Climer was a physical education teacher for many years and later competed in the Senior Olympics. To live to be 100, she says, it is important to stay focused on what is good now and not give in to negative thoughts. Ruth also believes that staying busy and always moving forward are keys to longevity (O'Dell, 2013).
- Billy Red Fox thinks that being active and not worrying are important keys to living to be 100. At 95, he switched jobs to become a public relations representative. Even at 100, he travels 11 months of the year making public appearances and talking with older adults (Segerberg, 1982).
- Simo Radulovich thinks that living to an old age requires having a sense of humor, living moderately, and sleeping well. He continues to engage in exercise games with his friends every day and says he has never been afraid of anything but always had confidence that he could get through the tough times (O'Dell, 2013).
- Mary Butler says that finding something to laugh about every day has helped her live longer. She thinks a good laugh is better than a dose of medicine anytime (Segerberg, 1982).
- Duran Baez remarried at 50 and went on to have 15 more children. At 100 years of age, he was asked if he had any ambitions he had not yet realized. Duran replied, "No" (Segerberg, 1982).
- Jeanne Louise Calment, the world's longest-living person who died at 122, attributed her longevity to a number of things: Don't worry about things you can't do anything about. Enjoy an occasional glass of port wine and a diet rich in olive oil. Laugh often. Regarding her ability to live so long, she once said that God must have forgotten about her. On her 120th birthday, an interviewer asked her what kind of future she anticipated. Jeanne Louise replied, "A very short one." Becoming accustomed to the media attention she got, at 117 she stated, "I wait for death . . . and journalists." She walked, biked, and exercised regularly. Jeanne Louise began taking fencing lessons at 85 and rode a bicycle until she was 100.

(a)

(b)

(a) Frenchwoman Jeanne Louise Calment, shown here celebrating her 117th birthday, was the oldest documented living person. She lived to be 122 years of age. (b) Simo Radulovich, 103 years of age in 2013, says that the best thing about living past 100 is being able to enjoy family and friends. He and his wife were married more than 60 years.

(a) ©Jean Pierre Fizet/Sygma/Getty Images; (b) Courtesy of The Radulovich Family

In 2018, the oldest living person in the world was 117-year-old Nabi Tajima of Japan. The oldest living person in the United States was 114-year-old Delphine Gibson of Pennsylvania.

What chance do you have of living to be 100? Genes play an important role in surviving to an extreme old age (Park & others, 2018; Patel & others, 2018). As we saw in the chapter on “Biological Beginnings,” the search for longevity genes has recently intensified (Benetos, 2019; Blankenburg, Pramstaller, & Domingues, 2018; Whitfield & Thorpe, 2017). But there are additional factors at work, such as family history, health (weight, diet, smoking, and exercise), education, personality, stress, and lifestyle (Divo & others, 2018; Jove & others, 2017; Scott & others, 2018; Vidacek & others, 2017). Recall that in the epigenetic approach, there is an increased focus on determining gene  $\times$  environment ( $G \times E$ ) interactions that influence development (Bacalini & others, 2017; Jasiulionis, 2018; Kirkland & Meyer-Ficca, 2018; Moore, 2017). A recent Chinese study found that a combination of particular FOXO genotypes and drinking tea was associated with the prevention of cognitive decline in the oldest-old, aged 92+ (Zeng & others, 2016).

To further examine the factors that are involved in living to a very old age, let’s journey to the island of Okinawa in the East China Sea where individuals live longer than anywhere else in the world. In Okinawa, there are 34.7 centenarians for every 100,000 inhabitants, the highest ratio in the world. In comparison, the United States has about 10 centenarians for every 100,000 residents. The life expectancy in Okinawa is 81.2 years (86 for women, 78 for men), also one of the highest in the world.

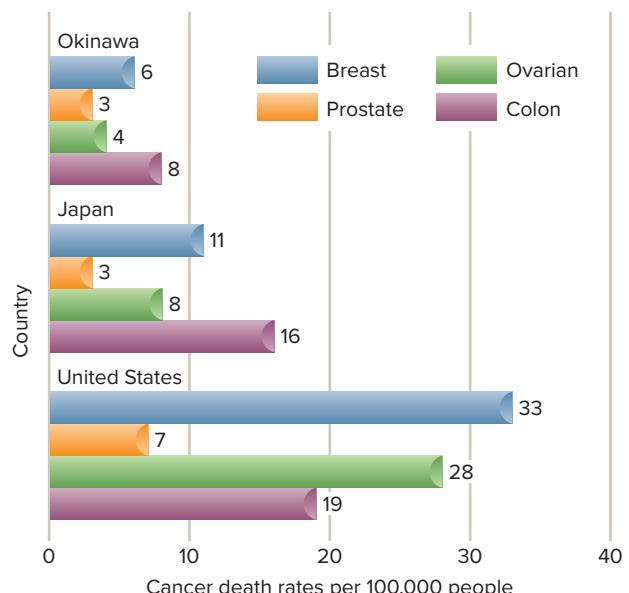

What is responsible for such longevity in Okinawa? Some possible explanations include the following (Nishihara & others, 2016; Willcox & Willcox, 2014; Willcox & others, 2007, 2008):

- **Diet.** Okinawans eat very healthy food, heavy on grains, fish, and vegetables, light on meat, eggs, and dairy products. This diet actually produces mild caloric restriction (10 to 15 percent) (Willcox & Willcox, 2014). The risk of dying from cancer is far lower among Okinawans than among Japanese and Americans (see Figure 2). About 100,000 Okinawans moved to Brazil during the mid-twentieth century and quickly adopted the eating regimen of their new home, one heavy on red meat. The result: The life expectancy of the Brazilian Okinawans is now 17 years lower than Okinawa’s 81 years!
- **Low-stress lifestyle.** The easygoing lifestyle in Okinawa more closely resembles that of a laid-back South Sea island than that of the high-stress world on the Japanese mainland.
- **Caring community.** Okinawans look out for each other and do not isolate or ignore their older adults. If older adults need help, they don’t hesitate to ask a neighbor. Such support and caring is likely

## developmental connection

### Heredity

Scientists are increasing their search for genes that are linked to how long people are likely to live. Connect to “Biological Beginnings.”

**FIGURE 2**

### RISKS OF DYING FROM CANCER IN OKINAWA, JAPAN, AND THE UNITED STATES.

The risk of dying from different forms of cancer is lower in Okinawa than in the United States and Japan (Willcox, Willcox, & Suzuki, 2002). Okinawans eat lots of tofu and soy products, which are rich in flavonoids (substances that are believed to lower the risk of breast and prostate cancer). They also consume large amounts of fish, especially tuna, mackerel, and salmon, which reduces the risk of breast cancer.

Source: Willcox, B.J., Willcox, M.D., & Suzuki, M. (2002). *The Okinawa Program*. New York: Crown.

responsible for Okinawa having the lowest suicide rate among older women in East Asia, an area noted for its high suicide rate among older women.

- *Activity.* Many older adults in Okinawa are physically vigorous, engaging in activities such as taking walks and working in their gardens. Many older Okinawans also continue working at their jobs.
- *Spirituality.* Many older adults in Okinawa find a sense of purpose in spiritual practice. Prayer is commonplace and believed to ease the mind of stress and problems.

## THE YOUNG-OLD AND THE OLDEST-OLD

Do you want to live to be 100, or 90? These ages are part of late adulthood, which begins in the sixties and extends to approximately 120 to 125 years of age. This is the longest span of any period of human development—50 to 60 years. Increasingly, a distinction is being made

between the *young-old* (65 to 84 years of age) and *oldest-old* (85 years and older). An increased interest in successful aging is producing a portrayal of the oldest-old that is more optimistic than past stereotypes (Carstensen, 2014, 2015; Ferdows, Jensen, & Tarraf, 2018; Kim, Park, & Park, 2017; Pollock & others, 2018; Rowe & Kahn, 2015). Interventions such as cataract surgery and a variety of rehabilitation strategies are improving the functioning of the oldest-old (Bakondi & others, 2017). And there is cause for optimism in the development of new regimens of prevention and intervention, such as engaging in regular exercise (Erickson & Liu-Ambrose, 2016; Erickson & Oberlin, 2017; Preston, Reynolds, & Pearson, 2018).

Many experts on aging prefer to talk about the categories of young-old and oldest-old in terms of *function* rather than age. Recall that we have described age not only in terms of chronological age but also in terms of biological age, psychological age, and social age. Thus, in terms of *functional age*—the person's actual ability to function—an 85-year-old might well be more biologically and psychologically fit than a 65-year-old.

Still, there are some significant differences between adults in their sixties or seventies and adults who are 85 and older. Paul Baltes and his colleagues (Baltes, 2003; Scheibe, Freund, & Baltes, 2007) argue that the oldest-old (85 and over) face a number of problems, including sizable losses in cognitive potential and ability to learn; an increase in chronic stress; a substantial prevalence of physical and mental disabilities; high levels of frailty; increased loneliness; and the difficulty of dying with dignity at older ages. He contrasts the problems of the oldest-old with the increase in successful aging of adults in their sixties and seventies. Compared with the oldest-old, the young-old have a substantial potential for physical and cognitive fitness, higher levels of emotional well-being, and more effective strategies for mastering the gains and losses of old age.

The oldest-old today are mostly female, and the majority of these women are widowed and live alone if they are not institutionalized. A recent list (2017) of the oldest people alive today in the world had no men in the top 25. The majority also are hospitalized at some time in the last years of life, and the majority die alone in a hospital or institution. Their needs, capacities, and resources are often different from those of older adults in their sixties and seventies (Scheibe, Freund, & Baltes, 2007).

Despite the negative portrait of the oldest-old by Baltes and his colleagues, they are a heterogeneous, diversified group (Lindahl-Jacobsen & Christensen, 2019; Ribeiro & Araujo, 2019). In the New England Centenarian Study, 15 percent of the individuals 100 years and older were living independently at home, 35 percent with family members or in assisted living, and 50 percent in nursing homes (Perls, 2007).

A significant number of the oldest-old have cognitive impairments, but many do not (Meija & others, 2017; Nosraty & others, 2018). Almost one-fourth of the oldest-old are institutionalized, and many report some limitation of activity or difficulties in caring for themselves. However, more than three-fourths are not institutionalized. The majority of older adults aged 80 and over continue to live in the community. More than one-third of older adults 80 and over who live in the community report that their health is excellent or good; 40 percent say that they have no activity limitations (Suzman & others, 1992). A substantial subgroup of the oldest-old are robust and active. The oldest-old who have aged successfully have often been unnoticed and unstudied.

Teru Kingjo, 88, continues to work as a weaver on Okinawa Island, Japan. She, like many Okinawans, believes that having a sense of purpose helps people to live longer.

### developmental connection

#### Nature and Nurture

The nature-nurture issue is a key aspect of understanding development throughout the human life span. Connect to “Introduction” and “Biological Beginnings.”

## BIOLOGICAL THEORIES OF AGING

Even if we stay remarkably healthy, we begin to age at some point. In fact, some life-span experts argue that biological aging begins at birth (Schaie, 2000). What are the biological explanations of aging? Intriguing explanations of why we age are provided by these biological theories: evolutionary theory, genetic/cellular process theories, and hormonal stress theory.

**Evolutionary Theory of Aging** Recall from “Biological Beginnings” the view that the benefits conferred by evolutionary selection decrease with age (Baltes, 2003). In the **evolutionary theory of aging**, natural selection has not eliminated many harmful conditions and non-adaptive characteristics in older adults (Greenberg & Vatolin, 2018; Vanhaelen, 2015; Yanai & others, 2017). Why? Because natural selection is linked to reproductive fitness, which is present only in the earlier part of adulthood. For example, consider Alzheimer disease, an irreversible brain disorder that does not appear until late middle adulthood or late adulthood. In evolutionary theory, if Alzheimer disease occurred earlier in development, it might have been eliminated many centuries ago. Evolutionary theory, however, has its critics (Cohen, 2015). One criticism is that the “big picture” idea of natural selection leading to the development of human traits and behaviors is difficult to refute or test because evolution occurs on a time scale that does not lend itself to empirical study. Another criticism is the failure of evolutionary theory to account for cultural influences (Singer, 2016).

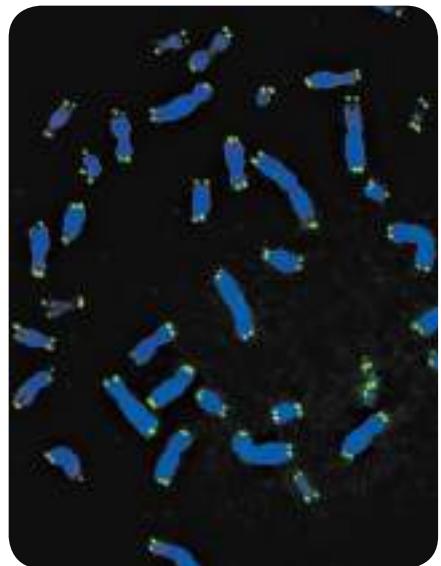

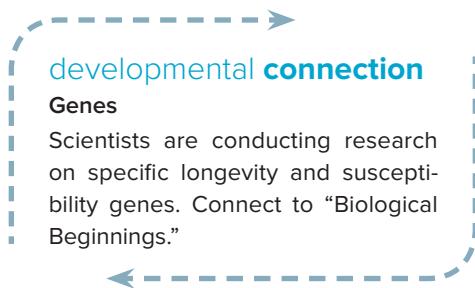

**Genetic/Cellular Process Theories** One recent view stated that aging is best explained by cellular maintenance requirements and evolutionary constraints (Vanhaelen, 2015). In recent decades, there has been a significant increase in research on genetic and cellular processes involved in aging (Brunet & Rando, 2017; Falandry, 2019; Hernandez-Segura, Nehme, & Demaria, 2018; Ong & Ramasamy, 2018). Five such advances involve telomeres, free radicals, mitochondria, sirtuins, and the mTOR pathway.

**Cellular Clock/Telomere Theory** **Cellular clock theory** is Leonard Hayflick’s (1977) theory that cells can divide a maximum of about 75 to 80 times, and that as we age our cells become less capable of dividing. Hayflick found that cells extracted from adults in their fifties to seventies divided fewer than 75 to 80 times. Based on the ways cells divide, Hayflick places the upper limit of the human life-span potential at about 120 to 125 years of age.

In the last decade, scientists have tried to fill a gap in cellular clock theory (Nene & others, 2018; Touponce & Benetos, 2019; Zgheib & others, 2018). Hayflick did not know why cells die. The answer may lie at the tips of chromosomes, at telomeres, which are DNA sequences that cap chromosomes (Gonzales-Ebsen, Gregersen, & Olsen, 2017; Liu, 2017).

Each time a cell divides, the telomeres become shorter and shorter (Chang & Blau, 2018; Opresko & Shay, 2017) (see Figure 3). After about 70 or 80 replications, the telomeres are dramatically reduced, and the cell no longer can reproduce. The consensus of research is that telomere shortening does play a role in aging (De Vitis, Berardinelli, & Sgura, 2018; Matsumoto & others, 2018; Yang, Song, & Johnson, 2016). For example, one study revealed that healthy centenarians had longer telomeres than unhealthy centenarians (Terry & others, 2008). Further, a recent study confirmed that shorter telomere length was linked to Alzheimer disease (Scarabino & others, 2017). And previous research even indicated that shorter telomere length was linked to having worse social relationships, being less optimistic, and showing greater hostility (Uchino & others, 2012; Zalli & others, 2014).

Injecting the enzyme telomerase into human cells grown in the laboratory has been found to substantially extend the life of the cells beyond the approximately 70 to 80 normal cell divisions (Harrison, 2012). However, telomerase is present in approximately 85 to 90 percent of cancerous cells and thus may not produce healthy life extension of cells (Akincilar, Unal, & Tergaonkar, 2016; Cleal, Norris, & Baird, 2018; Haraguchi & others, 2017; Ozturk, Li, & Tergaonkar, 2017). To capitalize on the high presence of telomerase in cancerous cells, researchers currently are investigating telomerase-related gene therapies that inhibit telomerase and lead to the death of cancerous cells while keeping healthy cells alive (Barthel & others, 2017; de Vitis, Berardinelli, & Sgura, 2018; Pestana & others, 2017; Roh & others, 2017). A recent focus of these gene therapies is on stem cells and their renewal (Li & Denchi, 2018; Liu, 2017; Okada & others, 2016). Telomeres and telomerase are increasingly thought to be key components of the stem cell regeneration process, providing a possible avenue to restrain cancer and delay aging (Gunes, Avila, & Rudolph, 2018; Li & others, 2017; Marion & others, 2017; Ozturk, Li, & Tergaonkar, 2017; Zhou & others, 2018).

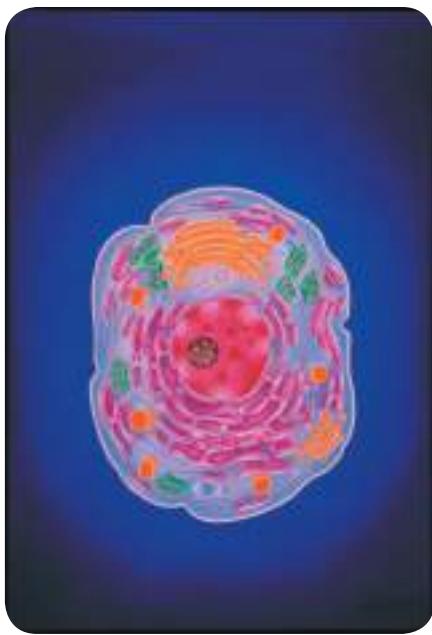

**FIGURE 3**

**TELOMERES AND AGING.** The photograph shows actual telomeres lighting up the tips of chromosomes.  
Courtesy of Dr. Jerry Shay

**evolutionary theory of aging** This theory states that natural selection has not eliminated many harmful conditions and nonadaptive characteristics in older adults; thus, the benefits conferred by evolution decline with age because natural selection is linked to reproductive fitness.

**cellular clock theory** Leonard Hayflick’s theory that the maximum number of times that human cells can divide is about 75 to 80. As we age, our cells have less capacity to divide.

**FIGURE 4**

**MITOCHONDRIA.** This color-coded illustration of a typical cell shows mitochondria in green. The illustration also includes the nucleus (pink) with its DNA (brown). *In what ways might changes in mitochondria be involved in aging?*

©J. Bavosi/Science Source

**free-radical theory** A microbiological theory of aging that states that people age because normal metabolic processes within their cells produce unstable oxygen molecules known as free radicals. These molecules ricochet around inside cells, damaging DNA and other cellular structures.

**mitochondrial theory** The theory that aging is caused by the decay of mitochondria, tiny cellular bodies that supply energy for function, growth, and repair.

**sirtuins** A family of proteins that have been proposed as having important influences on longevity, mitochondria functioning in energy, calorie restriction benefits, stress resistance, and cardiovascular functioning.

**mTOR pathway** A cellular pathway involving the regulation of growth and metabolism that has been proposed as a key aspect of longevity

**hormonal stress theory** The theory that aging in the body's hormonal system can decrease resistance to stress and increase the likelihood of disease.

**Free-Radical Theory** A second microbiological theory of aging is **free-radical theory**, which states that people age because when cells metabolize energy, the by-products include unstable oxygen molecules known as *free radicals*. The free radicals ricochet around the cells, damaging DNA and other cellular structures (Guillaumet-Adkins & others, 2017; Jabeen & others, 2018; Jeremic & others, 2018). The damage can lead to a range of disorders, including cancer and arthritis (Hegedus & others, 2018; Phull & others, 2018; Saha & others, 2017). Overeating is linked with an increase in free radicals, and researchers recently have found that calorie restriction—a diet restricted in calories but adequate in proteins, vitamins, and minerals—reduces the oxidative damage created by free radicals (Kalsi, 2015). In addition to diet, researchers also are exploring the role that exercise might play in reducing oxidative damage in cells (Robinson & others, 2017). A study of obese men found that endurance exercise reduced their oxidative damage (Samjoo & others, 2013).

**Mitochondrial Theory** There is increasing interest in the role that *mitochondria*—tiny bodies within cells that supply essential energy for function, growth, and repair—might play in aging (Hamilton & Miller, 2017; Mora, Bueno, & Rojas, 2017; Zole & Ranka, 2018) (see Figure 4). **Mitochondrial theory** states that aging is due to the decay of mitochondria. Mitochondrial theory views emphasizes that this decay is primarily caused by oxidative damage and loss of critical micronutrients supplied by the cell (Kim, Triolo, & Hood, 2017; Kim & others, 2017).

Defects in mitochondria are linked with cardiovascular disease (Anupama, Sindhu, & Raghu, 2018), neurodegenerative diseases such as Alzheimer disease (Birnbaum & others, 2018) and Parkinson disease (Larsen, Hanss, & Kruger, 2018), diabetic kidney disease (Forbes & Thorburn, 2018), and impaired liver functioning (Borrelli & others, 2018). Mitochondria likely play important roles in neuronal plasticity (Srivastava & others, 2018). However, it is not known whether the defects in mitochondria cause aging or are merely accompaniments of the aging process (Brand, 2011).

**Sirtuin Theory** **Sirtuins** are a family of proteins that have been linked to longevity, regulation of mitochondria functioning in energy, possible benefits of calorie restriction, stress resistance, and lower rates of cardiovascular disease and cancer (Ansari & others, 2017; Blank & Grummt, 2017; Ong & Ramasamy, 2018; Sarikhani & others, 2018; Wood & others, 2018). Later in the chapter, we will discuss one of the sirtuins, SIRT 1, that has been connected to DNA repair and aging.

**mTOR Pathway Theory** The **mTOR pathway** is a cellular pathway that involves the regulation of growth and metabolism. TOR stands for “target of rapamycin,” and in mammals it is called mTOR. Rapamycin is a naturally derived antibiotic and immune system suppressant/modulator that was discovered in the 1960s on Easter Island. It has been commonly used and is FDA approved for preventing rejection of transplanted organs and bone marrow (Shen & others, 2017). Recently, proposals have been made that the mTOR pathway has a central role in the life of cells, acting as a cellular router for growth, protein production/metabolism, and stem cell functioning (Houssaini & others, 2018; Kraig & others, 2018; Lim & others, 2017; Zhang & others, 2017). Some scientists also argue that the pathway is linked to longevity, the successful outcomes of calorie restriction, and reducing cognitive decline, and that it plays a role in a number of diseases, including cancer, cardiovascular disease, and Alzheimer disease (Maid & Power, 2018; Tramutola, Lanzillotta, & Di Domenico, 2017; Van Skike & others, 2018; Wang & others, 2017). The rapamycin drug has not been approved as an anti-aging drug and has some serious side effects, including increased risk of infection and lymphoma, a deadly cancer.

Some critics argue that scientific support has not been found for the role of sirtuins and the mTOR pathway in the aging process in humans and that research has not adequately documented the use of drugs such as rapamycin to slow the aging process or extend the human life span (Ehninger, Neff, & Xie, 2014).

**Hormonal Stress Theory** Cellular clock, free-radical, mitochondrial, sirtuin, and mTOR pathway theories attempt to explain aging at genetic and cellular levels. In contrast, **hormonal stress theory** argues that aging in the body's hormonal system can lower resistance to stress and increase the likelihood of disease (Finch & Seeman, 1999).

When faced with external challenges such as stressful situations, the human body adapts by altering internal physiological processes (Kim, Jee, & Pikhart, 2018; Steptoe & others, 2017). This process of adaptation and adjustment is referred to as *allostasis*. Allostasis is

adaptive in the short term; however, continuous accommodation of physiological systems in response to stressors may result in *allostatic load*, a wearing down of body systems due to constant activity (Edes & Crews, 2017; Goldstein & Kopin, 2018).

Normally, when people experience stressors, the body responds by releasing certain hormones. As people age, the hormones stimulated by stress remain at elevated levels longer than they did when people were younger (Gekle, 2017). These prolonged, elevated levels of stress-related hormones are associated with increased risks for many diseases, including cardiovascular disease, cancer, diabetes, and hypertension (Burleson, 2017; Castagne & others, 2018; Steptoe & others, 2017). Researchers are exploring stress-buffering strategies, including exercise, in an effort to find ways to attenuate some of the negative effects of stress on the aging process (Erickson & Oberlin, 2017; Gomes & others, 2017; Kim, Jee, & Pikhart, 2018; Niraula, Sheridan, & Godbout, 2017).

Recently, a variation of hormonal stress theory has emphasized the role of a decline in immune system functioning with aging (Fulop & others, 2019; Garschall & Flatt, 2018; Jasiliionis, 2018; Masters & others, 2017; Picard & McEwen, 2018). In a recent study, the percentage of T cells (a type of white blood cell essential for immunity) decreased in older adults in their seventies, eighties, and nineties (Song & others, 2018). Aging contributes to immune system deficits that give rise to infectious diseases in older adults (Le Page & others, 2018). The extended duration of stress and diminished restorative processes in older adults may accelerate the effects of aging on immunity.

**Conclusions** Which of these biological theories best explains aging? That question has yet to be answered. It likely will turn out that more than one—or perhaps all—of these biological processes contribute to aging. In a recent analysis, it was concluded that aging is a very complex process involving multiple degenerative factors, including interacting cell- and organ-level communications (de Magalhaes & Tacutu, 2016). Although there are some individual aging triggers such as telomere shortening, a full understanding of biological aging encompasses multiple processes operating at different biological levels.

## Review Connect Reflect

**LG1** Characterize longevity and discuss the biological theories of aging.

### Review

- What is the difference between life span and life expectancy? What characterizes centenarians? What sex differences exist in longevity?
- How can the differences between the young-old and oldest-old be summarized?
- What are the five main biological theories of aging?

### Connect

- Go back to Figure 1 and see if you can link any of the items listed with

research or theories you read about in this section or in earlier chapters (for example, item 2 states “If you are married, add four years,” and earlier we read that “Individuals who are happily married live longer, healthier lives than either divorced individuals or those who are unhappily married”).

### Reflect Your Own Personal Journey of Life

- To what age do you think you will live? Why? To what age would you like to live?

## 2 The Course of Physical Development in Late Adulthood

The Aging Brain

Sleep

Physical Appearance and Movement

LG2

Describe how a person’s brain and body change in late adulthood.

Sensory Development

The Circulatory and Respiratory Systems

Sexuality

The physical decline that accompanies aging usually occurs slowly, and sometimes lost function can even be restored. We’ll examine the main physical changes behind the losses of late adulthood and describe ways that older adults can age successfully.

## THE AGING BRAIN

How does the brain change during late adulthood? Does it retain plasticity?

**The Shrinking, Slowing Brain** On average, the brain loses 5 to 10 percent of its weight between the ages of 20 and 90. Brain volume also decreases (Liu & others, 2017; Peng & others, 2016). One study found a decrease in total brain volume and volume in key brain structures such as the frontal lobes and hippocampus from 22 to 88 years of age (Sherwood & others, 2011). Another study found that the volume of the brain was 15 percent less in older adults than in younger adults (Shan & others, 2005). Recent analyses concluded that in healthy aging the decrease in brain volume is due mainly to shrinkage of neurons, lower numbers of synapses, reduced length and complexity of axons, and reduced tree-like branching in dendrites, but only to a minor extent attributable to neuron loss (Penazzi, Bakota, & Brandt, 2016; Skaper & others, 2017). Of course, neuron loss occurs in individuals with disorders such as Alzheimer disease (Moore & Murphy, 2016; Poulakis & others, 2018). Further, in a recent study, global brain volume predicted mortality in a large population of stroke-free community-dwelling adults (Van Elderen & others, 2016).

Some areas of the brain shrink more than others (Peng & others, 2016). The prefrontal cortex is one area that shrinks the most with aging, and recent research has linked this shrinkage with decreased working memory and slower motor behavior in older adults (Hoyer, 2015). The sensory regions of the brain—such as the primary visual cortex, primary motor cortex, and somatosensory cortex—are less vulnerable to the aging process (Rodrique & Kennedy, 2011).

A general slowing of function in the brain and spinal cord begins in middle adulthood and accelerates in late adulthood (Salthouse, 2017; Yang, Bender, & Raz, 2015). Both physical coordination and intellectual performance are affected. For example, after age 70 many adults no longer show a knee jerk reflex, and by age 90 most reflexes are much slower (Spence, 1989). The slowing of the brain can impair the performance of older adults on intelligence tests and various cognitive tasks, especially those that are timed (Lu & others, 2011). For example, a neuroimaging study revealed that older adults were more likely to be characterized by slower processing in the prefrontal cortex during retrieval of information on a cognitive task than were younger adults (Rypma, Eldreth, & Rebbechi, 2007).

Historically, as in the research just discussed, much of the focus on links between brain functioning and aging has been on volume of brain structures and regions. Today, increased emphasis is being given to changes in myelination and neural networks (Anthony & Lin, 2018; Grady, 2017; Habeck & others, 2018; Madden & Parks, 2017). Recent research indicates that demyelination (a deterioration in the myelin sheath that encases the axons and is associated with information processing) of the brain occurs with aging in older adults (Callaghan & others, 2014; Cercignani & others, 2017; Rodrique & Kennedy, 2011).

Aging has also been linked to reduced synaptic functioning and decreased production of some neurotransmitters, including acetylcholine, dopamine, and gamma-aminobutyric acid (GABA) (Kamal & others, 2017). Reductions in acetylcholine have been linked to small declines in memory functioning and to the severe memory loss associated with Alzheimer disease, which will be further discussed in the chapter on “Cognitive Development in Late Adulthood” (Lewis, van Schalkwyk, & Bloch, 2017). Normal age-related reductions in dopamine may cause problems in planning and carrying out motor activities (Juhasz & others, 2017). Severe reductions in the production of dopamine have been linked with age-related diseases characterized by a loss of motor control, such as Parkinson disease (da Silva & others, 2018). GABA helps to control the precision of the signal sent from one neuron to another, decreasing “noise,” and its production decreases with aging (Rozyccka & Liguz-Lecznar, 2017).

**The Adapting Brain** The story of the aging brain is far from being limited to loss and decline in functioning. The aging brain also has remarkable adaptive capabilities (Erickson & Oberlin, 2017; Garaschuk, Semchyshyn, & Lushchak, 2018; Ishi & others, 2018; Kinugawa, 2019). Even in late adulthood, the brain loses only a portion of its ability to function, and the activities older adults engage in can influence the brain’s development (Borsa & others, 2018; Lovden, Backman, & Lindenberger, 2017; Reuter-Lorenz & Lustig, 2017). For example, in one fMRI study, higher levels of aerobic fitness were linked with greater volume in the hippocampus, which translates into better memory (Erickson & others, 2009). Also, a recent study found that a higher level of aerobic fitness embedded in a health promotion program for older adults was associated with higher cortical and hippocampal volumes (Carlson & others, 2015).

### developmental connection

#### Brain Development

Substantial growth in the prefrontal cortex occurs throughout infancy, childhood, and adolescence. Connect to “Physical Development in Infancy”; “Physical and Cognitive Development in Early Childhood”; “Physical and Cognitive Development in Middle and Late Childhood”; and “Physical and Cognitive Development in Adolescence.”

Three topics reflect the adaptiveness of the human brain in older adults: (1) the possibility that the brain might be able to generate new neurons, (2) the role of dendritic growth, and (3) the adaptive potential of delateralization.

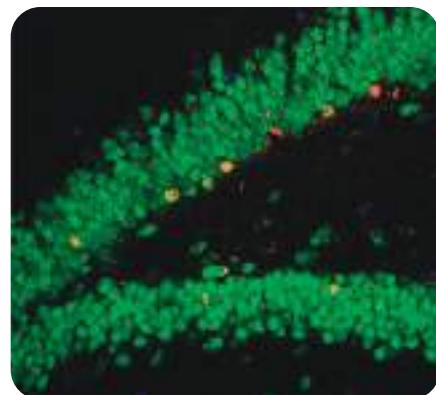

Can the brains of adults, even aging adults, generate new neurons? Researchers have found that **neurogenesis**, the generation of new neurons, does occur in lower mammalian species, such as mice (Adlof & others, 2017; O'Leary & others, 2018). Also, research indicates that exercise and an enriched, complex environment can generate new brain cells in rats and mice, and that stress reduces the survival rate of these new cells (Abbink & others, 2017; O'Leary & others, 2018; Park & others, 2018; Ruitenberg & others, 2017; Zhang & others, 2018) (see Figure 5). For example, in a recent study, mice in an enriched environment learned more flexibly because of adult hippocampal neurogenesis (Garthe, Roeder, & Kempermann, 2016). An earlier study revealed that coping with stress stimulated hippocampal neurogenesis in adult monkeys (Lyons & others, 2010). Researchers also have discovered that if rats are cognitively challenged to learn something, new brain cells survive longer (Shors, 2009).

It also is now accepted that neurogenesis can occur in human adults (Horgusluoglu & others, 2017; Shohayeb & others, 2018; Su, Dhananjaya, & Tarn, 2018). However, researchers have documented neurogenesis in only two brain regions: the hippocampus (Bowers & Jessberger, 2016; Olesen & others, 2017), which is involved in memory, and the olfactory bulb (Bonzano & De Marchis, 2017), which is involved in smell. It also is not known what functions these new brain cells perform, and at this point researchers have documented that they last for only several weeks (Nelson, 2006). Researchers currently are studying factors that might inhibit or promote neurogenesis, including various drugs, stress, and exercise (Liu & Nusslock, 2018; Tharmaratnam & others, 2017; Zhou & others, 2017). They also are examining how the grafting of neural stem cells to various regions of the brain, such as the hippocampus, might increase neurogenesis (Akers & others, 2018; Zhang & others, 2017). Research attention also is being directed to the possible role neurogenesis might play in slowing the impairment caused by neurodegenerative diseases such as Alzheimer disease, Parkinson disease, and Huntington disease (Ma & others, 2017; Shohayeb & others, 2018; Zheng & others, 2017).

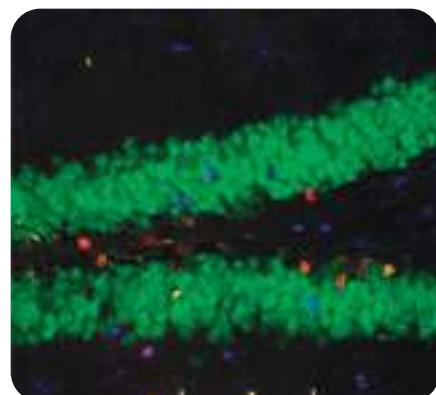

Dendritic growth can occur in human adults, possibly even in older adults (Eliasieh, Liets, & Chalupa, 2007). Recall that dendrites are the receiving portion of the neuron. One study compared the brains of adults at various ages (Coleman, 1986). From the forties through the seventies, the growth of dendrites increased. However, among people in their nineties dendritic growth no longer occurred. This dendritic growth might compensate for the possible loss of neurons through the seventies but not during the nineties. Lack of dendritic growth in older adults could be due to a lack of environmental stimulation and activity. Further research is needed to clarify precisely how dendrites change during aging.

Changes in lateralization may provide one type of adaptation in aging adults (Hong & others, 2015). Recall that lateralization is the specialization of function in one hemisphere of the brain or the other. Using neuroimaging techniques, researchers found that brain activity in the prefrontal cortex is lateralized less in older adults than in younger adults when they are engaging in cognitive tasks (Cabeza, 2002; Cabeza & Dennis, 2013; Park & Farrell, 2016; Sugiura, 2016). For example, Figure 6 shows that when younger adults are given the task of recognizing words they have previously seen, they process the information primarily in the right hemisphere; in contrast, older adults are more likely to use both hemispheres (Madden & others, 1999). The decrease in lateralization in older adults likely plays a compensatory role in the aging brain. That is, using both hemispheres may improve the cognitive functioning of older adults.

Of course, there are individual differences in how the brain changes in older adults (Nyberg, Pudas, & Lundquist, 2017; Wang, X., & others, 2018). Consider highly successful business executive 85-year-old T. Boone Pickens, who continued to lead a very active lifestyle, regularly exercising and engaging in cognitively complex work. Pickens underwent an fMRI in cognitive neuroscientist Denise Park's laboratory, during which he was presented with various cognitive tasks. Instead of both hemispheres being active, his left hemisphere was dominant, just as is the case for most younger adults (Helman, 2008). On tough questions—such as “Are ‘zombies’ and ‘unicorns’ living or nonliving?”—Pickens was relying mainly on the left hemisphere of his brain to make a decision. Indeed, as the cognitive tasks became more complex, Pickens was more likely to use the left hemisphere of his brain.

Exercise

Enriched Environment

## FIGURE 5

### GENERATING NEW NERVE CELLS IN

**ADULT MICE.** Researchers have found that exercise (running) and an enriched environment (a larger cage and many toys) can cause brain cells in adult mice to divide and form new brain cells (Kempermann, van Praag, & Gage, 2000). Cells were labeled with a chemical marker that becomes integrated into the DNA of dividing cells (red). Four weeks later, they were also labeled to mark neurons (nerve cells). As shown here, both the running mice and the mice in an enriched environment had many cells that were still dividing (red) and others that had differentiated into new nerve cells (orange). Does staying intellectually challenged affect one’s quality of life and longevity? To read further about aging and the brain, see *Connecting Through Research*.

## SLEEP

Fifty percent or more of older adults complain of having difficulty sleeping, which can have detrimental effects on their lives (Farajinia & others, 2014). In a recent analysis of sleep patterns from 20 to 90 years of age, total sleep decreased about 8 minutes per decade for males and about 10 minutes per decade for females as they got older (Dorffner, Vitr, & Anderer, 2015). Also in this study, as individuals aged, they engaged in more light sleep and less deep sleep. Researchers also have found that older adults’ sleep is more easily disrupted than that of younger adults (it takes longer for older adults to fall asleep initially, they wake up more often during the night, and they have greater difficulty going back to sleep) (McRae & others, 2016). Further, the significant reduction in deep sleep in older adults is more likely to occur in men than women (Redline & others, 2004). And in a recent study, when older adults slept 6 hours per day or less they were more likely to have fair or poor health (Lauderdale & others, 2016).

Sleep factors are linked to many aspects of older adults’ lives (Bao & others, 2017; Brewster, Riegel, & Gehrman, 2018; Dean & others, 2017; Hamasaki & others, 2017; Li, Vitiello, & Gooneratne, 2018). A recent research review concluded that female gender, depressed mood, and physical illness were the most consistently identified risks for future sleep problems in older adults (Smagula & others, 2016).

Poor sleep is a risk factor for falls, obesity, a lower level of cognitive functioning, and earlier death (Miner & Kryger, 2017; Onen & Onen, 2018). Research reviews indicate that improving older adults’ sleep through behavioral and pharmaceutical treatments may enhance their cognitive skills (Dzierzewski, Dautovich, & Ravits, 2018; Pace-Schott & Spencer, 2011). Further, one study revealed poor quality of sleep in individuals with mild cognitive impairment, which in some cases is a precursor for Alzheimer disease (Hita-Yanez, Atienza, & Cantero, 2013). In another study, sleep duration of more than seven hours per night in older adults was linked to longer telomere length, which was similar to the telomere length of middle-aged adults (Cribbet & others, 2014). Also, in one recent study, insomnia was associated with shorter telomere length in 70- to 88-year-olds but not in adults younger than 70 years old (Carroll & others, 2016). And a recent study revealed that even just one night of partial sleep deprivation activated DNA damage characteristic of biological aging (Carroll & others, 2015).

However, excessively long sleep duration also is often an indicator of less effective physical and cognitive functioning (Lo & others, 2016; Tsapanou & others, 2017). In a recent study, long sleep duration predicted an increase in all-cause mortality in individuals 65 years and older (Beydoun & others, 2017). Recent research indicated that when older adults slept 10 hours a day or more, they were more likely to have cardiovascular disease and diabetes (Han & others, 2016; Yang & others, 2016). And in a recent study, older adults who slept 9 hours or more a day had lower cognitive functioning (Malek-Ahmadi & others, 2016). Also, a recent Korean study revealed that sleeping 9 hours or longer per day was linked to a higher incidence of sarcopenia (Kwon & others, 2017). In general, it now appears that when older adults sleep less than 7 hours or more than 9 hours a night, their cognitive functioning is harmed (Lo & others, 2016).

Many of the sleep problems of older adults are associated with health problems (Kang, Lee, & Lim, 2017; Kato & others, 2017; Onen & Onen, 2018). Strategies to help older adults sleep better at night include avoiding caffeine, avoiding over-the-counter sleep remedies, staying physically active during the day, staying mentally active, and limiting naps (Hsiao & others, 2018; Morin, Savard, & Ouellet, 2013). In addition, one study of older adults indicated that walking at or above the internationally recommended level of 150 minutes per week predicted a lower likelihood of sleep onset or sleep maintenance problems four years later (Hartescu, Morgan, & Stevenson, 2016). And a recent Chinese study revealed that older adults who engaged in a higher level of overall physical activity, leisure-time exercise, and household activity were less likely to have sleep problems (Li & others, 2018).

## PHYSICAL APPEARANCE AND MOVEMENT

In late adulthood, the changes in physical appearance that began occurring during middle age become more pronounced. Wrinkles and age spots are the most noticeable changes.

# connecting through research

## Does Engaging in Intellectually Challenging Activities Affect Quality of Life and Longevity?

The Nun Study, directed by David Snowdon, is an intriguing ongoing investigation of aging in 678 nuns, many of whom live in a convent in Mankato, Minnesota (Keohane & Balfe, 2017; Latimer & others, 2017; Neltner & others, 2016; Pakhomov & Hemmy, 2014; Snowdon, 2003; Tyas & others, 2007; White & others, 2016). Each of the 678 nuns agreed to participate in annual assessments of her cognitive and physical functioning. They also agreed to donate their brains for scientific research when they die, and they are the largest group of brain donors in the world. Examination of the nuns' donated brains, as well as brains donated by others, has led neuroscientists to believe that the brain has a remarkable capacity to change and grow, even in old age. The Sisters of Notre Dame in Mankato lead intellectually challenging lives, and brain researchers believe this contributes to their quality of life as older adults and possibly increases their longevity.

Findings from the Nun Study so far include the following:

- Higher levels of idea density, a measure of linguistic ability assessed through autobiographies written in early adulthood (at age 22), were linked with higher brain weight, fewer incidences of mild cognitive impairment, and fewer characteristics of Alzheimer disease in 75- to 95-year-old nuns (Riley & others, 2005).
- Positive emotions early in adulthood were linked to longevity (Danner, Snowdon, & Friesen, 2001). Handwritten autobiographies from 180 nuns, composed when they were 22 years of age, were scored for emotional content. The nuns whose early writings had higher scores for positive emotional content were more likely to still be alive at 75 to 95 years of age than their counterparts whose early writings were characterized by negative emotional content.

(b)

(a) Sister Marcella Zachman (*left*) finally stopped teaching at age 97. Now, at 99, she helps ailing nuns exercise their brains by quizzing them on vocabulary or playing a card game called Skip-Bo, at which she deliberately loses. Sister Mary Esther Boor (*right*), also 99 years of age, is a former teacher who stays alert by doing puzzles and volunteering to work the front desk. (b) A technician holds the brain of a deceased Mankato nun. The nuns donate their brains for research that explores the effects of stimulation on brain growth.

©James Balog

- Sisters who had taught for most of their lives showed more moderate declines in intellectual skills than those who had spent most of their lives doing service-based tasks, which supports the notion that stimulating the brain with intellectual activity keeps neurons healthy and alive (Snowdon, 2002).

This study and other research provides hope that scientists will discover ways to tap into the brain's capacity to adapt in order to prevent and treat brain diseases (Alexopoulos & Kelly, 2017; Liu & others, 2017; Wang, X., & others, 2018). For example, scientists might learn more effective ways to improve older adults' cognitive functioning, reduce Alzheimer disease, and help older adults recover from strokes (DeSimone & others, 2017; Gmial & others, 2018; Methgal & others, 2018; Sperling, 2017). Even when areas of the brain are permanently damaged by stroke, new message routes can be created to get around the blockage or to resume the function of that area, indicating that the brain does adapt.

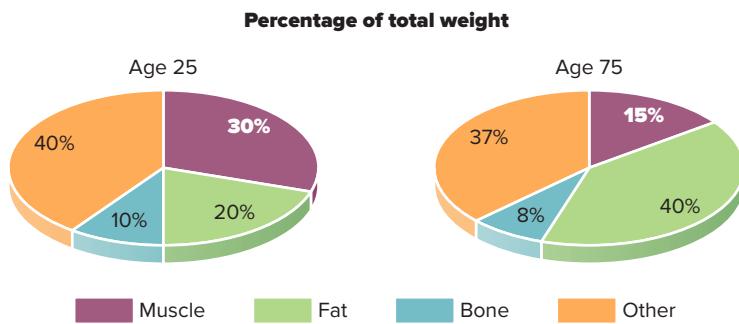

We also become shorter as we get older. Both men and women become shorter in late adulthood because of bone loss in their vertebrae (Hoyer & Roodin, 2009).

Our weight usually drops after we reach 60 years of age. This likely occurs because of muscle loss, which also gives our bodies a "sagging" look (Evans, 2010). Figure 7 shows the declining percentage of muscle and bone from age 25 to age 75, and the corresponding increase in the percentage of fat. One study found that long-term aerobic exercise was linked with greater muscle strength in 65- to 86-year-olds (Crane, Macneil, & Tarnopolsky, 2013). In another study, at-risk overweight and obese older adults lost significant weight and improved their mobility considerably by participating in a community-based weight reduction program (Rejeski & others, 2017).

#### Biological Processes

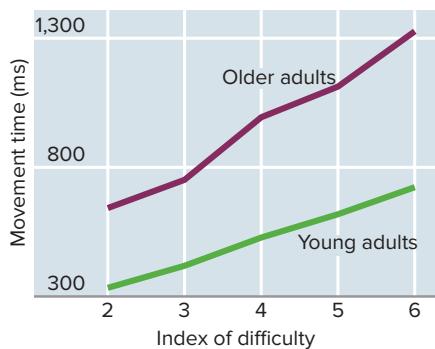

On average, men lose 1 to 2 inches in height from 30 to 70 years of age and women can lose as much as 2 inches in height from age 25 to 75. Connect to "Physical and Cognitive Development in Middle Adulthood."

**FIGURE 7**

#### CHANGES IN BODY COMPOSITION OF BONE, MUSCLE, AND FAT

**FROM 25 TO 75 YEARS OF AGE.** Notice the decrease in bone and muscle and the increase in fat from 25 to 75 years of age.

**FIGURE 8**

**MOVEMENT AND AGING.** Older adults take longer to move than young adults, and this change occurs across a range of movement difficulty (Ketcham & Stelmach, 2001).

Older adults move more slowly than young adults, and this slowing occurs for movements with a wide range of difficulty (Davis & others, 2013) (see Figure 8). Adequate mobility is an important aspect of maintaining an independent and active lifestyle in late adulthood (Danilovich & others, 2018; Gray-Miceli, 2017). Recent research indicates that obesity contributes to mobility limitations in older adults (Anson & others, 2017; JafariNasabian & others, 2017). The good news is that regular walking decreases the onset of physical disability and reduces functional limitations in older adults (Mullen & others, 2012). For example, a recent study of older adults found that walking a dog regularly was associated with better physical health (Curl, Bibbo, & Johnson, 2017). Exercise also benefitted frail elderly adults in another study (Danilovich, Conroy, & Hornby, 2018). In this study, high-intensity walking training reduced the older adults' frailty, increased their walking speed, and improved their balance. And in another recent study, a 10-week exercise program improved the physical capabilities (aerobic endurance, agility, and mobility) and cognitive function (selective attention and planning) of elderly nursing home residents (Pereira & others, 2018).

The risk of falling in older adults increases with age and is greater for women than for men (Francis-Coad & others, 2017; Gouveia & others, 2017). Falls are the leading cause of injury deaths among adults who are 65 years and older (National Center for Health Statistics, 2018). Each year, approximately 200,000 adults over the age of 65 (many of them women) fracture a hip in a fall. Half of these older adults die within 12 months, frequently from pneumonia.

A recent meta-analysis found that exercise reduces falls in adults 60 years of age and older (Stubbs, Brefka, & Denkinger, 2015). And in one study, walking was more effective than balance training in reducing falls in older adults (Okubo & others, 2016).

## SENSORY DEVELOPMENT

Seeing, hearing, and other aspects of sensory functioning are linked with our ability to perform everyday activities (Hochberg & others, 2012). This link was documented in a study of more than 500 adults, 70 to 102 years of age, in which sensory acuity, especially visual capacity, was related to whether and how well older adults bathed and groomed themselves, completed household chores, engaged in intellectual activities, and watched TV (Marsiske, Klumb, & Baltes, 1997). How do vision, hearing, taste, smell, touch, and sensitivity to pain change in late adulthood?

**Vision** Recently, researchers have found that visual decline in late adulthood is linked to (a) cognitive decline (Monge & Madden, 2016; Roberts & Allen, 2016), and (b) having fewer social contacts and engaging in less challenging social/leisure activities (Cimarolli & others, 2017). Also, with aging, visual acuity, color vision, and depth perception decline. Several diseases of the eye may emerge in aging adults.

**Visual Acuity** In late adulthood, the decline in vision that began for most adults in early or middle adulthood becomes more pronounced (Jensen & Tubaek, 2017). Visual processing speed declines in older adults (Bezdicek & others, 2016). Night driving is especially difficult, to some extent because of diminishing sensitivity to contrasts and reduced tolerance for glare (Kimlin, Black, & Wood, 2017). Dark adaptation is slower—that is, older individuals take longer to recover their vision when going from a well-lighted room to semidarkness. The area of the visual field becomes smaller, a change suggesting that the intensity of a stimulus in the peripheral area of the visual field needs to be increased if the stimulus is to be seen. Events taking place away from the center of the visual field might not be detected (West & others, 2010).

This visual decline often can be traced to a reduction in the quality or intensity of light reaching the retina (Nag & Wadhwa, 2012). At 60 years of age, the retina receives only about one-third as much light as it did at 20 years of age (Scialfa & Kline, 2007). In extreme old age, these changes might be accompanied by degenerative changes in the retina, causing severe difficulty in seeing. Large-print books and magnifiers might be needed in such cases.

Recent research has shown that sensory decline in older adults is linked to a decline in cognitive functioning (Wongrakpanich, Petchorian, & Rosenzweig, 2016). Also, one study of individuals in their seventies revealed that visual decline was related to slower speed of processing information, which in turn was associated with greater cognitive decline (Clay & others, 2009).

**Color Vision** Color vision also may decline with age in older adults as a result of the yellowing of the lens of the eye (Scialfa & Kline, 2007). This decline is most likely to occur in the green-blue-violet part of the color spectrum. As a result, older adults may have trouble accurately distinguishing between objects of closely related colors, such as navy blue socks and black socks.

**Depth Perception** As with many types of perception, depth perception changes little after infancy until adults become older. Depth perception typically declines in late adulthood, which can make it difficult for the older adult to determine how close or far away or how high or low something is (Bian & Anderson, 2008). A decline in depth perception can make steps or street curbs difficult to manage.

**Diseases of the Eye** Three diseases that can impair the vision of older adults are cataracts, glaucoma, and macular degeneration:

- **Cataracts** involve a thickening of the lens of the eye that causes vision to become cloudy, opaque, and distorted (Radhakrishnan & others, 2018). By age 70, approximately 30 percent of individuals experience a partial loss of vision due to cataracts. Initially, cataracts can be treated by glasses; if they worsen, the cloudy lens should be surgically removed and replaced with an artificial one (Jiang & others, 2018; Singh, Dohlman, & Sun, 2017). A recent Japanese study found that older adults (mean age: 76 years) who had cataract surgery were less likely to develop mild cognitive impairment than their counterparts who had not had the surgery (Miyata & others, 2018). Also, diabetes is a risk factor for the development of cataracts (Becker & others, 2018; Chua & others, 2017).
- **Glaucoma** involves damage to the optic nerve because of the pressure created by a buildup of fluid in the eye (Jiang & others, 2018; Koh & others, 2017). Approximately 1 percent of individuals in their seventies and 10 percent of those in their nineties have glaucoma, which can be treated with eye drops. If left untreated, glaucoma can ultimately destroy a person's vision.
- **Macular degeneration** involves deterioration of the macula of the retina, which corresponds to the focal center of the visual field. Individuals with macular degeneration may have relatively normal peripheral vision but be unable to see clearly what is right in front of them (Owsley & others, 2016) (see Figure 9). This condition affects 1 in 25 individuals from 66 to 74 years of age and 1 in 6 of those 75 years old and older. One study revealed that cigarette smoking contributes to macular degeneration (Schmidt & others, 2006). If the disease is detected early, it can be treated with laser surgery (Hernandez-Zimbron & others, 2018). However, macular degeneration is difficult to treat and thus is a leading cause of blindness in older adults. Also, there is increased interest in using stem-cell-based therapy for macular degeneration (Apatoff & others, 2018; Bakondi & others, 2017; Mandai, Kurimoto, & Takahashi 2017).

**Hearing** For hearing as for vision, the age of older adults is important in determining the degree of decline (Hoffman & others, 2017; Wingfield & Lash, 2016) (see Figure 10). The decline in vision and hearing is much greater in individuals 75 years and older than in individuals 65 to 74 years of age (Charness & Bosman, 1992).

Hearing impairment usually does not become much of an impediment until late adulthood (Johnson, Xu, & Cox, 2017). Only 19 percent of individuals from 45 to 54 years of age experience some type of hearing problem (Harris, 1975). By contrast, a national survey revealed that 63 percent of adults 70 years and older had a hearing loss defined as an inability to hear sounds at frequencies higher than 25 dB with their better ear (Lin & others, 2011). In this study, hearing aids were used by 40 percent of those with moderate hearing loss. Also, a recent study of 80- to 106-year-olds found a substantial increase in hearing loss in the ninth and then in the tenth decades of life (Wattamwar & others, 2017).

Older adults often don't recognize that they have a hearing problem, deny that they have one, or accept it as a part of growing old. Also, a study that spanned 10 years also found that

**cataracts** A thickening of the lens of the eye that causes vision to become cloudy, opaque, and distorted.

**glaucoma** Damage to the optic nerve because of the pressure created by a buildup of fluid in the eye.

**macular degeneration** A disease that involves deterioration of the macula of the retina, which corresponds to the focal center of the visual field.

Perceptual System	65 to 74 years	75 years and older
Vision	There is a loss of acuity even with corrective lenses. Less transmission of light occurs through the retina (half as much as in young adults). Greater susceptibility to glare occurs. Color discrimination ability decreases.	There is a significant loss of visual acuity and color discrimination, and a decrease in the size of the perceived visual field. In late old age, people are at significant risk for visual dysfunction from cataracts and glaucoma.
Hearing	There is a significant loss of hearing at high frequencies and some loss at middle frequencies. These losses can be helped by a hearing aid. There is greater susceptibility to masking of what is heard by noise.	There is a significant loss at high and middle frequencies. A hearing aid is more likely to be needed than in young-old age.

**FIGURE 10**

**VISION AND HEARING DECLINE IN LATE ADULTHOOD**

poor nutrition and a lifetime of smoking were linked to more rapid onset of hearing difficulties in older adults (Heine & others, 2013).

Hearing loss in older adults is linked to declines in activities of daily living, cognitive functioning, and language, as indicated by the results of the following research. Recent research has found that older adults' hearing problems are linked to impaired activities of daily living (Gopinath & others, 2012), less time spent out of home and in leisure activities (Mikkola & others, 2016), increased falls (Gopinath & others, 2016; Jiam, Li, & Agrawal, 2016), reduced cognitive functioning (Golub, 2017), and loneliness (Mick & others, 2018). Also, in a recent study, older adults' hearing aid use was associated with less loneliness (Weinstein, Sirow, & Moser, 2016).

What outcomes occur when older adults have dual sensory loss in vision and hearing? In a recent study of 65- to 85-year-olds, dual sensory loss in vision and hearing was linked to reduced social participation and less social support, as well as increased loneliness (Mick & others, 2018). In another recent study, this type of dual sensory loss in older adults (mean age of 82 years) involved greater functional limitations, increased loneliness, cognitive decline, and communication problems (Davidson & Guthrie, 2018). And in another recent study, older adults who had a dual sensory impairment involving vision and hearing had more depressive symptoms (Han & others, 2018).

**Smell and Taste** Most older adults lose some of their sense of taste or smell, or both (Correia & others, 2016). A recent national study of community-dwelling older adults revealed that 74 percent had impaired taste and 22 percent had impaired smell (Correia & others, 2016). These losses often begin around 60 years of age (Hawkes, 2006). A majority of individuals age 80 and older experience a significant reduction in smell (Lafreniere & Mann, 2009). Researchers have found that older adults show a greater decline in their sense of smell than in their sense of taste (Schiffman, 2007). Smell and taste decline less in healthy older adults than in their less healthy counterparts. A recent study found that a poorer sense of smell in older adults was associated with increased feelings of depression and loneliness (Sivam & others, 2016).

**Touch and Pain** Changes in touch and pain sensitivity are also associated with aging (Arneric & others, 2014). A recent national study of community-dwelling older adults revealed that 70 percent of older adults had impaired touch (Correia & others, 2016). One study found that with aging, individuals could detect touch less in the lower extremities (ankles, knees, and so on) than in the upper extremities (wrists, shoulders, and so on) (Corso, 1977). For most older adults, a decline in touch sensitivity is not problematic (Hoyer & Roodin, 2009). And one study revealed that older adults who are blind retain a high level of touch sensitivity, which likely is linked to their use of active touch in their daily lives (Legge & others, 2008).

An estimated 60 to 75 percent of older adults report at least some persistent pain (Molton & Terrill, 2014). The most frequent pain complaints of older adults are back pain (40 percent), peripheral neuropathic pain (35 percent), and chronic joint pain (15 to 25 percent) (Denard & others, 2010). The presence of pain increases with age in older adults, and women are more likely to report having pain than are men (Tsang & others, 2008). In a recent research review, it was concluded that older adults have lower pain sensitivity but only for lower pain intensities

(Lautenbacher & others, 2017). Older adults also are less sensitive to pain than are younger adults (Harkins, Price, & Martinelli, 1986). Although decreased sensitivity to pain can help older adults cope with disease and injury, it can also mask injuries and illnesses that need to be treated.

**Perceptual Motor Coupling** Perception and action are coupled throughout the life span. Driving a car illustrates the coupling of perceptual and motor skills. The decline in perceptual-motor skills in late adulthood makes driving a car difficult for many older adults (Lodha & others, 2016; Pozzi & others, 2018). Drivers over the age of 65 are involved in more traffic accidents than middle-aged adults because of mistakes such as improper turns, not yielding the right of way, and not obeying traffic signs; their younger counterparts are more likely to have accidents because they are speeding (Lavalliere & others, 2011; Sterns, Barrett, & Alexander, 1985). Older adults can compensate for declines in perceptual-motor skills by driving shorter distances, choosing less congested routes, and driving only in daylight.

An extensive research review evaluated the effectiveness of two types of interventions in improving older adults' driving: cognitive training and exercise (Ross, Schmidt, & Ball, 2013):

- *Cognitive training.* Cognitive training programs have shown some success in older adults, including improving their driving safety and making driving less difficult. In one study conducted by Karlene Ball and her colleagues (2010), training designed to enhance speed of processing produced more than a 40 percent reduction in at-fault crashes over a six-year period.
- *Education.* Results are mixed with regard to educational interventions that seek to improve older adults' driving ability and to reduce their involvement in traffic accidents (Gaines & others, 2011).

## THE CIRCULATORY AND RESPIRATORY SYSTEMS

Cardiovascular disorders increase in late adulthood (Lind & others, 2018). In older adults, 64 percent of men and 69 percent of women 65 to 74 years of age have hypertension (high blood pressure) (Centers for Disease Control and Prevention, 2018a). More than 70 percent of older adults who have a heart attack or stroke have preexisting hypertension.

Today, most experts on aging recommend that consistent blood pressures above 120/80 should be treated to reduce the risk of heart attack, stroke, or kidney disease (Krakoff, 2008). A rise in blood pressure with age can be linked to illness, obesity, stiffening of blood vessels, stress, or lack of exercise (Cheng & others, 2017). The longer any of these factors persist, the higher the individual's blood pressure gets.

Various drugs, a healthy diet, and exercise can reduce the risk of cardiovascular disease in many older adults (Georgioupolou & others, 2017; Kantoch & others, 2018). In a recent study of older adults, a faster exercise walking pace, not smoking, modest alcohol intake, and avoiding obesity were associated with a lower risk of heart failure (Del Gobbo & others, 2015). Another study revealed that diminished exercise capacity and lack of walking were the best predictors of earlier death in older adults with heart problems (Reibis & others, 2010). And in a recent study of adults 65 and older, a Mediterranean diet lowered their risk of cardiovascular problems (Nowson & others, 2018).

In the respiratory system, lung capacity drops 40 percent between the ages of 20 and 80, even when disease is not present (Fozard, 1992). Lungs lose elasticity, the chest shrinks, and the diaphragm weakens (Lalley, 2013). The good news, though, is that older adults can improve lung functioning with diaphragm-strengthening exercises. Severe impairments in lung functioning and death can result from smoking (Wilhelmsen & others, 2011).

## SEXUALITY

In the absence of two circumstances—disease and the belief that old people are or should be asexual—sexuality can be lifelong (Corona & others, 2013). Aging, however, does induce some changes in human sexual performance, more so in males than in females (Estill & others, 2017).

Orgasm becomes less frequent in males with age, occurring in every second to third attempt rather than every time. More direct stimulation usually is needed to produce an erection. From 65 to 80 years of age, approximately one out of four men have serious problems getting and/or keeping erections, and after 80 years of age the percentage rises to one out of two men (Butler & Lewis, 2002). However, with recent advances in erectile dysfunction

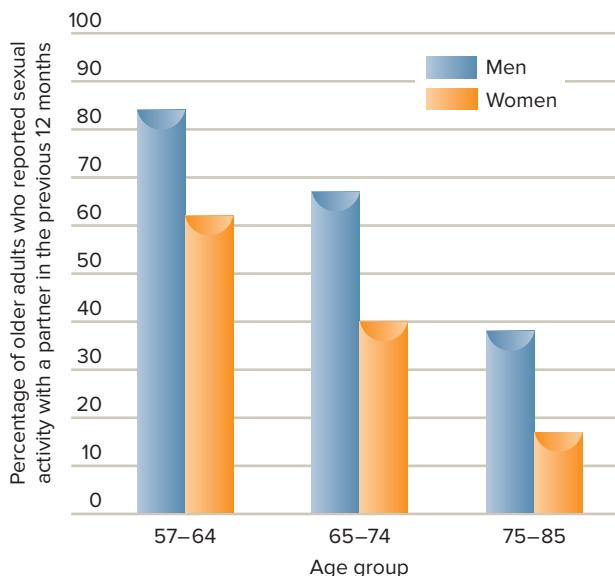

### developmental connection

#### Sexuality

Older adults may express their sexuality differently from younger adults, focusing on touching and caressing in their sexual relationship when sexual intercourse becomes difficult. Connect to "Socioemotional Development in Late Adulthood."

What are some characteristics of sexuality in older adults? How does sexuality change as men and women go through late adulthood?

**FIGURE 11**  
**SEXUAL ACTIVITY IN OLDER ADULTS WITH A PARTNER**

medications such as Viagra, an increasing number of older men, especially the young-old, are able to have an erection (Bennett, 2018; Constantinescu & others, 2017; Gesser-Edelsburg & Hijazi, 2018; Ozcan & others, 2017). Also, recent research suggests that declining levels of serum testosterone, which is linked to erectile dysfunction, can be treated with testosterone replacement therapy to improve sexual functioning in males (Gray, McHale, & Carre, 2017; Hackett & Kirby, 2018; Hackett & others, 2017; Jones & Kelly, 2018; Kaya & others, 2017; Mayo Clinic, 2018). However, the benefit-risk ratio of testosterone replacement therapy is uncertain for older males (Isidori & others, 2014).

A considerable portion of older adults remain sexually active (Thomas, Hess, & Thurston, 2015). An interview study of more than 3,000 adults 57 to 85 years of age revealed that many older adults are sexually active as long as they are healthy (Lindau & others, 2007). Sexual activity did decline through the later years of life: 73 percent of people 57 to 64 years old, 53 percent of people 65 to 74 years old, and 26 percent of adults 75 to 85 years old reported that they were sexually active. Even in the sexually active oldest group (75 to 85), more than 50 percent said they still have sex at least two to three times a month. Fifty-eight percent of sexually active 65- to 74-year-olds and 31 percent of 75- to 85-year-olds said they engage in oral sex. As with middle-aged and younger adults, older adults who did not have a partner were far less likely to be sexually active than those who had a partner. For older adults with a partner who reported not having sex, the main reason

was poor health, especially the male partner's physical health. Also, older adults are increasingly using online dating websites. A recent study of 4,000 dating profiles online found that older adults were more likely to use first-person plural pronouns (we, our), not be self-enhancing, focus more on connectedness and relationships with others, describe positive emotions, and use words associated with health than were younger adults when seeking a romantic partnership (Davis & Fingerman, 2016).

A large-scale study of individuals from 57 to 85 years of age revealed that sexual activity, a good-quality sexual life, and interest in sex were positively related to health in middle and late adulthood (Lindau & Gavrilova, 2010). Also in this study, these aspects of sexuality were higher for aging males than aging women, and this gap widened with age. Further, sexually active life expectancy was longer for men than women, but men lost more years of sexually active life due to poor health than women did.

As indicated in Figure 11, sexual activity with a partner declined from the last part of middle adulthood through late adulthood, with a lower rate of sexual activity with a partner for women than men. Indeed, a challenge for a sexually interested older woman is finding a partner. At 70 years of age, approximately 70 percent of women don't have a partner compared with only about 35 percent of men. Many older women's husbands have died, and many older men are in relationships with younger women.

## Review Connect Reflect

**LG2** Describe how a person's brain and body change in late adulthood.

### Review

- How much plasticity and adaptability does the aging brain have?
- What characterizes older adults' sleep?
- What changes in physical appearance and movement characterize late adulthood?
- How do vision, hearing, smell and taste, touch, and sensitivity to pain change in older adults?
- How do the circulatory and respiratory systems change in older adults?
- What is the nature of sexuality in late adulthood?

### Connect

- Many of the declines in the functioning of individuals in late adulthood start occurring in middle adulthood. Which declines in functioning occur mainly in late adulthood?

### Reflect Your Own Personal Journey of Life

How healthy are older adults? What types of health problems do they have, and what can be done to maintain or improve their health and ability to function in everyday life?

## HEALTH PROBLEMS

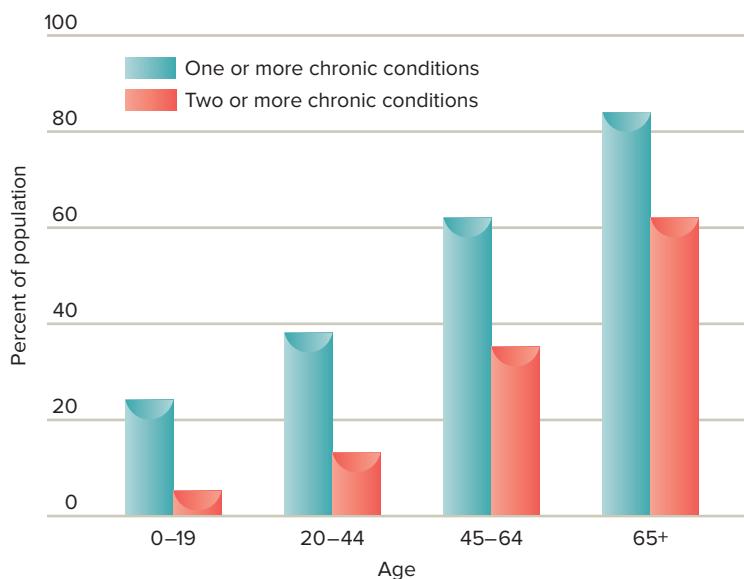

As we age, we become more susceptible to disease or illness (Baker & Petersen, 2018; Benetos & others, 2019; Hou & others, 2018; Skulachev & Skulachev, 2017). The majority of adults who are still alive at 80 years of age or older are likely to have some type of impairment. Chronic diseases (those with a slow onset and a long duration) are rare in early adulthood, increase in middle adulthood, and become more common in late adulthood (Hirsch & Sirois, 2016). As indicated in Figure 12, 84 percent of U.S. adults 65 years of age and older have one or more chronic conditions, and 62 percent have two or more chronic conditions (Partnership for Solutions, 2002).

As shown in Figure 13, arthritis is the most common chronic disorder in late adulthood, followed by hypertension. Older women have a higher incidence of arthritis and hypertension and are more likely to have visual problems, but are less likely to have hearing problems, than older men are.

Although adults over the age of 65 often have a physical impairment, many of them can still carry on their everyday activities or work. Chronic conditions associated with the greatest limitations on work are heart conditions (52 percent), diabetes (34 percent), asthma (27 percent), and arthritis (27 percent). Conflict in relationships has been linked with greater decline in older adults with diabetes or hypertension (Seeman & Chen, 2002). Low income is also strongly related to health problems in late adulthood (Ferraro, 2006). Approximately three times as many poor as non-poor older adults report that their activities are limited by chronic disorders. Recent studies document links between low socioeconomic status and health problems (Boylan, Cundiff, & Matthews, 2018; Caplan, Washington, & Swanner, 2017). One study revealed that frailty increased for low-income older adults, regardless of their ethnicity (Szanton & others, 2010).

**Causes of Death in Older Adults** Nearly 60 percent of deaths among U.S. adults 65 to 74 years are caused by cancer or cardiovascular disease. Cancer recently replaced cardiovascular disease as the leading cause of death in U.S. middle-aged adults. The decline in cardiovascular disease in middle-aged adults has been attributed to improved drugs, decreased rates of smoking, improved diets, and increased exercise (Georgiopoulou & others, 2017; Kantoch & others, 2018; Nowson & others, 2018). The same realignment of causes of death recently occurred in 65- to 74-year-olds, with cancer now the leading cause of death in this age group (Centers for Disease Control and Prevention, 2018c). However, in the 75-to-84 and 85-and-over age groups, cardiovascular disease is the leading cause of death (Centers for Disease Control and Prevention, 2018c). As individuals age through the late adult years, the older they are the more likely they are to die of cardiovascular disease rather than cancer.

Ethnicity is linked with the death rates of older adults (Centers for Disease Control and Prevention, 2018c). Among ethnic groups in the United States, African Americans have high death rates for stroke, heart disease, lung cancer, and female breast cancer. Asian Americans and Latinos have low death rates for these diseases. In the last decade, death rates for most diseases in African Americans, Latinos, and Asian Americans have decreased. However, death rates for most diseases remain high for African Americans (Centers for Disease Control and Prevention, 2018c).

**PERCENT OF U.S. POPULATION WITH CHRONIC CONDITIONS ACROSS AGE GROUPS**

How many of us older persons have really been prepared for the second half of life, for old age, and eternity?

—CARL JUNG

*Swiss Psychoanalyst, 20th Century*

**FIGURE 13**  
**THE MOST PREVALENT CHRONIC CONDITIONS IN MIDDLE AND LATE ADULTHOOD**

**Arthritis** **Arthritis** is an inflammation of the joints accompanied by pain, stiffness, and movement problems. Arthritis is especially common in older adults (Koyanagi & others, 2018). This disorder can affect hips, knees, ankles, fingers, and vertebrae. Individuals with arthritis often experience pain and stiffness, as well as problems in moving about and performing routine daily activities. There is no known cure for arthritis. However, the symptoms of arthritis can be reduced by drugs such as aspirin, range-of-motion exercises for the afflicted joints, weight reduction, and in extreme cases, replacement of the crippled joint with a prosthesis (Daien & others, 2017; Zhao, Mysler & Moots, 2018). Recent research has documented the benefits of exercise in older adults with arthritis (AbouAssi & others, 2017; Allen & others, 2018). A recent study of women found that leisure-time physical inactivity increased the risk for subsequent development of arthritis (Di Giuseppe & others, 2015). In this study, women with the highest levels of leisure-time activity were the least likely to develop arthritis. Also, a high-intensity, 16-week strength-training program significantly increased the strength and reduced the pain of arthritis patients (Flint-Wagner & others, 2009).

**Osteoporosis** Normal aging brings some loss of bone tissue, but in some instances loss of bone tissue can become severe (Fougere & Cesari, 2019; JafariNasabian & others, 2017). **Osteoporosis** involves an extensive loss of bone tissue. Osteoporosis is the main reason many older adults walk with a marked stoop. Women are especially vulnerable to osteoporosis, which is the leading cause of broken bones in women (Ballane & others, 2017; Madrasi & others, 2018). Approximately 80 percent of osteoporosis cases in the United States occur in females, and almost two-thirds of all women over the age of 60 are affected by osteoporosis. It is more common in non-Latina White, thin, and small-framed women.

Osteoporosis is related to deficiencies in calcium, vitamin D, and estrogen, and to lack of exercise (Kemmler, Engelke, & von Stengel, 2016). To prevent osteoporosis, young and middle-aged women should eat foods rich in calcium (such as dairy products, broccoli, turnip greens, and kale), exercise regularly, and avoid smoking (Garcia-Gomariz & others, 2018; Giangregorio & El-Kotob, 2017; Kemmler, Kohl, & von Stengel, 2017; Varahra & others, 2018). Drugs such as Fosamax can be used to reduce the risk of osteoporosis (Black & Rosen, 2016; Tu & others, 2018). Aging women should also get bone density checks.

**Accidents** Unintended injuries are the eighth leading cause of death among older adults (Centers for Disease Control and Prevention, 2018c). Injuries resulting from a fall at home or a traffic accident in which an older adult is a driver or an older pedestrian is hit by a vehicle are common. Falls are the leading cause of injury deaths among adults who are 65 years and older (Centers for Disease Control and Prevention, 2018c). Each year, approximately 200,000 adults over the age of 65 (most of them women) fracture a hip in a fall. Half of these older adults die within 12 months, frequently from pneumonia. Two-thirds of older adults who experience a fall are likely to fall again in the next six months.

## SUBSTANCE USE AND ABUSE

In many cases, older adults are taking multiple medications, which can increase the risks associated with consuming alcohol or other drugs. For example, when combined with tranquilizers or sedatives, alcohol use can impair breathing, produce excessive sedation, and be fatal. Optimization of drug use, especially not overdosing, is a key factor in successful aging (Marien & Spinewine, 2019).

How extensive is substance abuse in older adults? A national survey found that in 2010 the percentage of individuals who engaged in binge drinking (defined as four or more drinks for women and five or more drinks for men on one occasion in the past 30 days) declined considerably in middle and late adulthood (Centers for Disease Control and Prevention, 2012).

**arthritis** Inflammation of the joints accompanied by pain, stiffness, and movement problems; this disease is especially common in older adults.

**osteoporosis** A chronic condition that involves an extensive loss of bone tissue and is the main reason many older adults walk with a marked stoop.

(see Figure 14). However, the frequency of binge drinking in the past 30 days was highest among older adults (5.5 episodes).

Despite the decline in the percentage of individuals who engage in binge drinking in late adulthood, the Substance Abuse and Mental Health Services Administration (2003) has identified substance abuse among older adults as an “invisible epidemic” in the United States. The belief is that substance abuse often goes undetected in older adults, and there is concern about older adults who abuse not only illicit drugs but prescription drugs as well (Bien & Bien-Barkowska, 2018; DiBartolo & Jarosinski, 2017; Loscalzo & others, 2017; Petrovic & others, 2019). Too often, screening questionnaires are not appropriate for older adults, and the consequences of alcohol abuse—such as depression, inadequate nutrition, congestive heart failure, and frequent falls—may erroneously be attributed to other medical or psychological conditions (Hoyer & Roodin, 2009). Because of the dramatic increase in the number of older adults anticipated over the twenty-first century, substance abuse is likely to characterize an increasing number of older adults.

*Late-onset alcoholism* is the label used to describe the onset of alcoholism after the age of 65. Late-onset alcoholism is often related to loneliness, loss of a spouse, or a disabling condition.

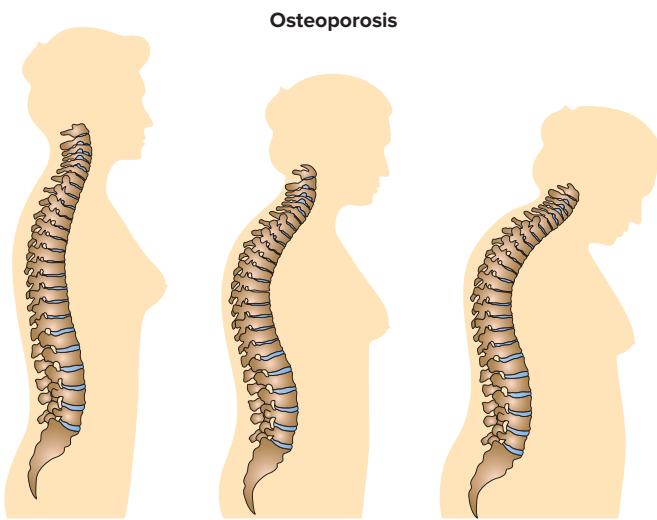

Researchers have found a protective effect of moderate alcohol use in older adults (O’Keefe & others, 2014). One study revealed better physical and mental health, and increased longevity in older adults who drank moderately compared with those who drank heavily or did not drink at all (Rozzini, Ranhoff, & Trabucchi, 2007). Benefits of moderate drinking include better physical well-being and mental performance, greater openness to social contacts, and ability to assert mastery over one’s life. A recent study of older adults found that moderate alcohol consumption was linked to greater volume in the brain’s hippocampus (Downer & others, 2015). Another recent study revealed that moderate drinkers were more likely to be alive and not have a cognitive impairment at 85 years of age (Richards & others, 2018). Another study in aging adults indicated that moderate wine consumption was associated with lower inflammatory risk factors related to cardiovascular disease across an 8-year period (Janssen & others, 2014).

Researchers have especially found that moderate drinking of red wine is linked to better health and increased longevity (Giacosa & others, 2016; Li, Li, & Lin, 2018; Liberale & others, 2017). Explanations of the benefits of red wine center on its role in lowering stress and reducing the risk of heart disease (Bitterman & Chung, 2015; Chen & others, 2017). Evidence is increasing that a chemical in the skin of red wine grapes—resveratrol—plays a key role in red wine’s health benefits (Giacosa & others, 2016; Li, Li, & Lin, 2018). One study found that red wine, but not white, killed several lines of cancer cells (Wallenborg & others, 2009). Scientists are exploring how resveratrol, as well as calorie restriction, increases SIRT 1, an enzyme that is involved in DNA repair and aging (Giacosa & others, 2016; Granchi & Minutolo, 2018; Liberale & others, 2017). Some critics argue that there is inconsistent evidence that resveratrol and SIRT 1 are linked to longevity (Tang & others, 2014).

## EXERCISE, NUTRITION, AND WEIGHT

Can exercise slow the aging process? Can eating a nutritious but calorie-reduced diet increase longevity? Let’s examine how exercise, nutrition, and weight control might influence how healthily we age.

**Exercise** Although we may be in the evening of our lives in late adulthood, we are not meant to live out our remaining years passively. Everything we know about older adults suggests that the more active they are, the healthier and happier they are likely to be (Cho, Post, & Kim, 2018; Erickson & Oberlin, 2017; Gill & others, 2016; Henderson & others, 2018; Strandberg, 2019).

What characterizes osteoporosis? What factors contribute to osteoporosis?

Age Group	Percent	Drinks Per Occasion	Frequency
18–24	28	9	4.2
25–34	28	8	4.2
35–44	19	8	4.1
45–64	13	7	4.7
65 & over	4	5	5.5

**FIGURE 14**

**BINGE DRINKING THROUGH THE LIFE SPAN.** Note: Percent refers to percent of individuals in a particular age group who engaged in binge drinking on an occasion in the past 30 days (4 or more drinks for women, 5 or more for men). Drinks per occasion reflects the intensity of the binge drinking. Frequency indicates the number of occasions in which binge drinking occurred in the past 30 days.

### Health

Being physically fit and cognitively fit are key aspects of successful aging. Connect to “Socioemotional Development in Late Adulthood.”

In one study, exercise literally made the difference between life and death for middle-aged and older adults. More than 10,000 men and women were divided into categories of low fitness, medium fitness, and high fitness (Blair & others, 1989). Then they were studied over a period of eight years. Sedentary participants (low fitness) were more than twice as likely to die during the eight-year time span of the study than those who were moderately fit and more than three times as likely to die as those who were highly fit. The positive effects of being physically fit occurred for both men and women in this study. Further, one study revealed that 60-year-old and older adults who were in the lowest fifth in terms of physical fitness as determined by a treadmill test were four times more likely to die over a 12-year period than their counterparts who were in the top fifth of physical fitness (Sui & others, 2007). A longitudinal study found that men who exercised regularly at 72 years of age had a 30 percent higher probability of still being alive at 90 years of age than their sedentary counterparts (Yates & others, 2008). And a study of more than 11,000 women found that low cardiorespiratory fitness was a significant predictor of death (Farrell & others, 2010). Also, a study of joggers in Copenhagen, Denmark, revealed that engaging in light or moderate jogging on a regular basis was linked to increased longevity (Schnohr & others, 2015). Further, in a recent study, relative to individuals with low physical fitness, those who increased from low to intermediate or high fitness were at a lower risk for all-cause mortality (Brawner & others, 2017).

Setting exercise goals and then carrying out an exercise plan are important not only in young adults but older adults as well. For example, a study of elderly women revealed that those who had set exercise-related personal goals were four times more likely to report high exercise activity eight years later (Saajanaho & others, 2014).

Gerontologists increasingly recommend strength training in addition to aerobic activity and stretching for older adults (Falck & others, 2017; Grgic & others, 2018). The average person's lean body mass declines with age—about 6.6 pounds of lean muscle are lost each decade during the adult years. The rate of loss accelerates after age 45. Resistance exercises can preserve and possibly increase muscle mass in older adults (Grgic & others, 2018; Nordheim & others, 2017). A recent study of older adults found that resistance training improved their physical function, psychological well-being, and quality of life (Pedersen & others, 2017).

Exercise is an excellent way to maintain health and live longer (Brawner & others, 2017; Erickson & Oberlin, 2017; Strandberg, 2019). The current recommendations for older adults' physical activity are 2 hours and 30 minutes of moderate-intensity aerobic activity (brisk walking, for example) per week and muscle-strengthening activities on two or more days per week (Centers for Disease Control and Prevention, 2018b). In the recent recommendations, even greater benefits can be attained with 5 hours of moderate-intensity aerobic activity per week.

Researchers continue to document the positive effects of exercise in older adults (Erickson & Oberlin, 2017; Frith & Loprinzi, 2018; Moreira & others, 2018; Strandberg, 2019). Exercise helps people to live independent lives with dignity in late adulthood (Henderson & others, 2018; Strasser & others, 2018). At 80, 90, and even 100 years of age, exercise can help prevent older adults from falling down or even being institutionalized (Hill & others, 2018). Being physically fit means being able to do the things you want to do, whether you are young or old. More about research on exercise's positive benefits for health is shown in Figure 15.

Researchers who study exercise and aging have made the following discoveries:

- *Exercise is linked to increased longevity.* A study of older adults found that total daily physical activity was linked to increased longevity across a four-year period (Buchman & others, 2012). In a longitudinal study of Chinese women, those who exercised regularly were less likely to die over a period of approximately six years (Matthews & others, 2007). Also, in one analysis, energy expenditure by older adults during exercise that burns up at least 1,000 calories a week was estimated to increase life expectancy by about 30 percent, while burning up 2,000 calories a week in exercise was estimated to increase life expectancy by about 50 percent (Lee & Skerrett, 2001).
- *Exercise is related to prevention of common chronic diseases.* Exercise can reduce the risk of developing cardiovascular disease, type 2 diabetes, osteoporosis, stroke, and breast cancer (Endes & others, 2016; Mora & Valencia, 2018). For example, a study of older adults found that a higher lifetime physical activity level reduced age-related decline in cardiovascular and respiratory functions (Bailey & others, 2013).
- *Exercise is associated with improvement in the treatment of many diseases.* When exercise is used as part of the treatment, individuals with these diseases show improvement in

**FIGURE 15**

### THE JOGGING HOG EXPERIMENT.

Jogging hogs reveal the dramatic effects of exercise on health. In one investigation, a group of hogs was trained to run approximately 100 miles per week (Bloor & White, 1983). Then the researchers narrowed the arteries that supplied blood to the hogs' hearts. The hearts of the jogging hogs developed extensive alternate pathways for blood supply, and 42 percent of the threatened heart tissue was salvaged, compared with only 17 percent in a control group of non-jogging hogs.

Courtesy of Maxine Bloor

symptoms: arthritis, pulmonary disease, congestive heart failure, coronary artery disease, hypertension, type 2 diabetes, obesity, and Alzheimer disease (Preston, Reynolds, & Pearson, 2018; Scott & others, 2018).

- *Exercise improves older adults' cellular functioning.* Researchers increasingly are finding that exercise improves cellular functioning in older adults (Broskey & others, 2017). For example, researchers recently have discovered that aerobic exercise is linked to greater telomere length in older adults (Denham, O'Brien, & Charchar, 2016). And one study found that aerobic exercise increased proteins related to mitochondrial functioning in older adults (Konopka & others, 2014).
- *Exercise improves immune system functioning in older adults* (Lancaster & Febbraio, 2016; Minuzzi & others, 2018). One study revealed that following exercise, a number of components of immune system functioning in older adult women improved (Sakamoto & others, 2009).
- *Exercise can optimize body composition and reduce the decline in motor skills as aging occurs.* Exercise can increase muscle mass and bone mass, improve balance and reduce falls, as well as decrease bone fragility (Cho & others, 2018; Sgro & others, 2018). One study found that participation in exercise activities was linked to a delay in the onset and progression of frailty (Peterson & others, 2009). Also, a recent study found that yoga-based exercise improved the balance and mobility of older adults (Youkhana & others, 2016). And a recent study found that an exercise program reduced the number of falls in older adults with dementia (Burton & others, 2015).
- *Exercise reduces the likelihood that older adults will develop mental health problems and can be effective in the treatment of mental health problems.* For example, a recent research review concluded that exercise reduces depressive symptoms in older adults (Seo & Chao, 2018). A recent study found that older adults who engaged in regular physical activity following a heart attack were less depressed than their counterparts who were more sedentary (Ernstsen & others, 2016). In another recent study, assisted living residents were less depressed after participating in a 4-week intervention involving Wii Fit exergames than were residents who had received a health education program (Chao & others, 2015).
- *Exercise can reduce the negative effects of stress in older adults* (Tada, 2018). One study revealed that older adults with a high level of stress who engaged in aerobic exercise had a lower cortisol level than their high-stress counterparts who did not engage in aerobic exercise (Heaney, Carroll, & Phillips, 2014).
- *Exercise is linked to improved brain, cognitive, and affective functioning in older adults.* Older adults who exercise regularly not only show better brain functioning but also process information more effectively than older adults who are more sedentary (Coetsee & Terblanche, 2018; Erickson & Oberlin, 2017; Smith, Hendy, & Tempest, 2018). In a recent research review on brain functioning, more physically fit and active older adults had superior memory functioning and a higher level of executive function than their sedentary counterparts (Erickson, Hillman, & Kramer, 2015).

Despite the extensive documentation of exercise's power to improve older adults' health and quality of life, a national survey in 2014 found that 65- to 74-year-olds exercised less than 25- to 64-year-olds and that the older adults continued to decrease their exercise at 75 years and older (Centers for Disease Control and Prevention, 2015). Nonetheless, older adults have increased the amount of time they exercise in recent years—in 2006 slightly more than 20 percent of 65- to 74-year-olds reported engaging in regular exercise but in 2014 that figure had increased to more than 40 percent (Centers for Disease Control and Prevention, 2008, 2015).

Possible explanations of older adults' reduction in exercise compared with middle-aged adults focus on such factors as chronic illnesses, life crises (such as a spouse's death) that disrupt exercise schedules, embarrassment at being around others who are in better shape (especially if they haven't exercised much earlier in life), and the "why bother?" factor (not believing that exercise will improve their lives much). But as we have seen, it is never too late to begin exercising, and older adults can significantly benefit from regular exercise (Erickson & Oberlin, 2017; Mora & Valencia, 2018).

**Nutrition and Weight** Four aspects of nutrition are especially important in older adults: (1) getting adequate nutrition, (2) avoiding overweight and obesity, (3) deciding whether to

Johnny Kelley finishing one of the many Boston Marathons he ran as an older adult. In 1991, he ran his sixtieth Boston Marathon, and in 2000 he was named "Runner of the Century" by *Runner's World* magazine. At 70 years of age, Kelley was still running 50 miles a week. At that point in his life, Kelley said, "I'm afraid to stop running. I feel so good. I want to stay alive." He lived 27 more years and died at age 97 in 2004.

What characterizes the current controversy about longevity and being overweight?  
©curtoicurto/Getty Images

restrict calorie intake to improve health and extend life, and (4) determining whether to take specific vitamin supplements to slow the aging process.

**Healthy Nutrition** Eating a healthy, balanced diet and taking appropriate vitamins are important in helping older adults maintain their health (Diekmann & Bauer, 2019). One change in eating behavior that can occur in older adults is a decrease in snacking between meals, which contributes to harmful weight loss, especially in women. Among the strategies for increasing weight gain in these women are the use of taste enhancers and calorie supplements between meals.

**Overweight and Obesity** A recent national survey found that 37 percent of U.S. adults 60 years of age and older were obese in 2011–2014 (Flegal & others, 2016). This figure is lower than the 40.2 percent for 40 to 59 years of age. In this recent survey, 34.9 percent of men and 38.8 percent of U.S. adults 60 years of age and older were obese. A large-scale study found a substantial link between being overweight/obese and having a higher mortality risk (Masters & others, 2013). However, some studies have reported that overweight adults live longer than normal-weight adults or that being overweight is not a risk factor for earlier death, especially in older adults (Chang & others, 2012). In a research meta-analysis, overweight was associated with lower all-cause mortality but obesity was associated with higher all-cause mortality (Flegal & others, 2013).

A magazine article even mentioned that chubby might be the new healthy (Kolata, 2007). It's not clear why a few extra pounds that place someone in the overweight category might be linked to longevity. Possibly for some older adults, such as those recovering from surgery or those who develop pneumonia, the extra pounds may be protective. Some researchers argue that research evidence revealing a link between being overweight and living longer is likely due to inclusion of participants who have preexisting diseases (sometimes labeled “reverse causality”) or sarcopenia (loss of lean body mass) (Greenberg, 2006).

Despite the several studies that have found a link between being overweight and living longer, the majority of studies have revealed that being overweight is a risk factor for an earlier death (Katzmarzyk & others, 2012; Masters & others, 2013; Rizzuto & Fratiglioni, 2014). For example, in a recent large-scale study, obesity was associated with shorter longevity and increased risk of death due to cardiovascular disease compared with normal-weight individuals (Khan & others, 2018). In another recent large-scale study, obesity, as well as high body mass index (BMI) and waist circumference, were linked to earlier death (Batsis & others, 2017). Also, another recent large-scale study indicated that earlier death characterized older adults who were overweight, obese, or had a higher waist-to-hip ratio (Bowman & others, 2017). And in yet another recent study, obese middle-aged and older adults were more likely to have chronic diseases and experience an earlier death than their normal-weight counterparts (Stenholm & others, 2017).

Obesity also is linked to the acceleration of diseases in many older adults (Gabbay, Slotki, & Shavit, 2015; Khan & others, 2018; Rossi & others, 2017; Stenholm & others, 2017). However, although the link between obesity and disease is present in older adults, the link is weaker than it is for young and middle-aged adults (Kalish, 2016). Researchers also consistently find that when individuals are overweight and fit, they have a much better health profile and greater longevity than those who are overweight and not fit (Sardinha & others, 2016). Some leading researchers now conclude that inactivity and low cardiorespiratory fitness are greater threats to health and longevity than being overweight (McAuley & Blair, 2011).

**Calorie Restriction** Some studies have shown that calorie restriction in laboratory animals (such as rats and roundworms) can increase the animals' longevity (Schreiber, O'Leary, & Kennedy, 2016; Someya & others, 2017). Research indicates that calorie restriction slows RNA decline during the aging process (Hou & others, 2016). And researchers have found that chronic problems with the cardiovascular system, kidneys, and liver appear at a later age when calories are restricted (Tanjak & others, 2017). In addition, some recent research indicates that calorie restriction may provide neuroprotection for an aging central nervous system (White & others, 2017). A recent study found that calorie restriction maintained more youthful functioning in the hippocampus, which is an important brain structure for memory (Schafer & others, 2015). Another study revealed that when older adults restricted their calorie intake for three months, their verbal memory improved (Witte & others, 2009).

No one knows for certain how calorie restriction works to increase the life span of animals. Some scientists suggest that it might lower the level of free radicals and reduce oxidative

stress in cells (Tanjak & others, 2017). For example, one study found that calorie restriction slowed the age-related increase in oxidative stress (Ward & others, 2005). Others argue that calorie restriction might trigger stress and a state of emergency called “survival mode” in which the body eliminates all unnecessary functions to focus only on staying alive (Schreiber, O’Leary, & Kennedy, 2016). This survival mode likely is the result of evolution in which calorie restriction allowed animals to survive periods of famine, and thus the genes remain in the genomes of animal and human species today (Chen & Guarente, 2007).

However, a 25-year longitudinal study conducted by the National Institute of Aging casts some doubt on whether a calorie-restricted diet will increase longevity (Mattison & others, 2012). In this study, monkeys who were fed 30 percent fewer calories did not live longer than a control group of monkeys. The researchers concluded that genes and diet composition are likely better predictors of longevity than calorie restriction per se.

The results in the National Institute of Aging study contrast with an ongoing study at the Wisconsin National Primate Research Center, which has reported a 30 percent improved survival rate for calorie-restricted monkeys (Colman & others, 2009). Whether similar very-low-calorie diets can stretch the human life span is not known (Picca, Pesce, & Lezza, 2017). In some instances, the animals in these studies ate 40 percent less than normal. In humans, a typical level of calorie restriction involves a 30 percent decrease, which translates to about 1,120 calories a day for the average woman and 1,540 for the average man.

Do underweight women and men live longer? One study revealed that women who were 20 pounds or more underweight lived longer even after controlling for smoking, hypertension, alcohol intake, and other factors (Wandell, Carlsson, & Theobald, 2009). In this study, underweight men did not live longer when various factors were controlled.

The research findings on the effects of calorie restriction in humans are mixed (Locher & others, 2014). Thus, an appropriate conclusion at this time is that further research is needed to definitively determine whether calorie restriction increases longevity, especially in humans.

***The Controversy Over Vitamins and Aging*** For years, most experts on aging and health argued that a balanced diet was all that was needed for successful aging; vitamin supplements were not recommended. However, there have been some proposals that certain vitamin supplements—mainly a group called “antioxidants,” which includes vitamin C, vitamin E, and beta-carotene—might help to slow the aging process and improve the health of older adults (Prasad, 2017; Xu & others, 2017).

The theory is that antioxidants counteract the cell damage caused by free radicals, which are produced both by the body’s own metabolism and by environmental factors such as smoking, pollution, and harmful chemicals in the diet (Jabeen & others, 2018; Jeremic & others, 2018; Tonnes & Trushina, 2017). When free radicals cause damage (oxidation) in one cell, a chain reaction of damage follows. Antioxidants are theorized to act much like a fire extinguisher, helping to neutralize free-radical activity and reduce oxidative stress (Da Costa, Badawi, & El-Sohemy, 2012).

What have research studies found about the role of antioxidants in health? In two recent studies, no link was found between antioxidant vitamin intake and mortality (Henriquez-Sanchez & others, 2016; Stepaniak & others, 2016). Additionally, recent research reviews have not supported the belief that antioxidant vitamin supplements can reduce the incidence of cancer and cardiovascular disease (Khodaeian & others, 2015; Paganini-Hill, Kawas, & Corrada, 2015). However, a meta-analysis of seven studies concluded that dietary intakes (not vitamin supplements) of vitamin E, C, and beta-carotene were linked to a reduced risk of Alzheimer disease (Li, Shen, & Ji, 2012).

There still are many uncertainties about the role of antioxidant vitamins in health (Conti & others, 2016; Otaegui-Arrazola & others, 2014). For example, it is unclear which vitamins should be taken, how large a dose should be taken, what restrictions should be applied, and so on. Critics also argue that the key experimental studies documenting the effectiveness of vitamins in slowing the aging process have not been conducted. The studies in this area thus far have been so-called population studies that are correlational rather than experimental in nature. Other factors—such as exercise, better health practices, and good nutritional habits—might be responsible for the positive findings about vitamins and aging rather than vitamins per se. Also, the free-radical theory is a theory and not a fact, and it is only one of a number of theories about why we age.

## connecting with careers

### Sarah Kagan, Geriatric Nurse

Sarah Kagan is a professor of nursing at the University of Pennsylvania School of Nursing. She provides nursing consultation to patients, their families, nurses, and physicians regarding the complex needs of older adults related to their hospitalization. She also consults on research and the management of patients who have head and neck cancers. Kagan teaches in the undergraduate nursing program, where she directs a course on “Nursing Care in the Older Adult.” In 2003, she was awarded a MacArthur Fellowship for her work in the field of nursing.

Kagan says her work has allowed her the privilege of being with patients at the best and worst times of their lives. In the United States, older adults comprise close to half of all hospital stays, a quarter of ambulatory visits, and more than 70 percent of home health services. Many hospitals now employ emergency room staff who specialize in geriatric health care, and some offer separate geriatric emergency departments focused on treating older adults and reducing repeat admissions. The number of elders in developing countries is also expected to rise, from 400 million in 2000 to 1.7 billion by 2050—making geriatric health care a global issue.

For more information about what geriatric nurses do, see the *Careers in Life-Span Development* appendix.

## HEALTH TREATMENT

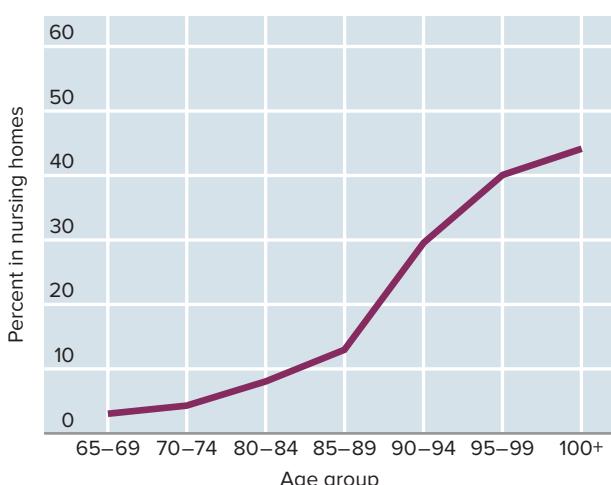

The increase in the aging population is predicted to dramatically escalate health-care costs over the foreseeable future. As older adults live longer, disease management programs will need to be expanded to handle the chronic disorders of older adults. The increasing demand for health services among the expanding population of older adults is likely to bring shortages of many types of health care professionals, including geriatric nurses, doctors, and health-care aides.

What is the quality of health treatment that older adults in the United States receive? A study of older adults with health problems revealed that they receive the recommended medical care they need only half the time (Wenger & others, 2003). The researchers examined the medical

records of 372 frail older adults who had been treated by two managed-care organizations over the course of one year. Then they documented the medical care each patient received and judged it using standard indicators of quality. For example, many older adults with an unsteady gait didn't get the help they needed, such as physical therapy to improve their walking ability. Clearly, the quality of health treatment provided to older adults needs to be significantly improved.

Geriatric nurses can be especially helpful in treating the health-care problems of older adults. To read about the work of one geriatric nurse, see *Connecting with Careers*.

The development of alternative home and community-based care has decreased the percentage of older adults who live in nursing homes (Walters & others, 2017). Still, as older adults age, their probability of being in a nursing home increases (see Figure 16). The quality of nursing homes and other extended-care facilities for older adults varies enormously and is a source of ongoing concern (Marshall & Hale, 2018; Wangmo, Nordstrom, & Kressig, 2017). More than one-third of these facilities are seriously deficient. They fail federally mandated inspections because they do not meet the minimum standards for physicians, pharmacists, and various rehabilitation specialists (occupational and physical therapists). Further concerns focus on the patient's

**FIGURE 16**  
PERCENTAGE OF U.S. OLDER ADULTS OF DIFFERENT AGES  
IN NURSING HOMES

## Health-Care Providers and Older Adults

The demand for home-care aides is predicted to increase dramatically in the next several decades because of the likely doubling of the 65-and-older population and older adults' preference for remaining out of nursing homes (Moos, 2007). The attitudes of both the health-care provider and the older adult are important aspects of the older adult's health care (Agrali & Akyar, 2014; Cagle & others, 2016; Clark, 2015). Unfortunately, health-care providers too often share society's stereotypes and negative attitudes toward older adults (Eymard & Douglas, 2012). In a health-care setting, these attitudes can take the form of avoidance, dislike, and begrimed tolerance rather than positive, hopeful treatment. Health-care personnel are more likely to be interested in treating younger persons, who more often have acute problems with a higher prognosis for successful recovery. They often are less motivated to treat older persons, who are more likely to have chronic problems with a lower prognosis for successful recovery.

Not only are physicians less responsive to older patients, but older patients often take a less active role in medical encounters with health-care personnel than do younger patients. Older adults should be encouraged to take a more active role in their own health care.

Not only is it important to increase the number of health-care professionals available to treat older adults, but it is also very important that they show positive attitudes toward them.

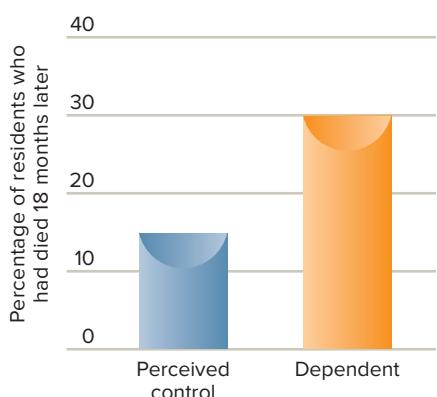

©jonya/Getty Images

right to privacy, access to medical information, safety, and lifestyle freedom within the individual's range of mental and physical capabilities.

Because of the inadequate quality of many nursing homes and the escalating costs for nursing home care, many specialists in the health problems of the aged stress that home health care, elder-care centers, and preventive medicine clinics are good alternatives (Nordstrom & Wangmo, 2018). They are potentially less expensive than hospitals and nursing homes (Rotenberg & others, 2018). They also are less likely to engender the feelings of depersonalization and dependency that occur so often in residents of institutions. Currently, there is an increased demand for, but shortage of, home-care workers because of the increase in the population of older adults and their preference to stay out of nursing homes (Franzosa, Tsui, & Baron, 2018; Hewko & others, 2015).

In a classic study, Judith Rodin and Ellen Langer (1977) found that an important factor related to health, and even survival, in a nursing home is the patient's feelings of control and self-determination. A group of elderly nursing home residents were encouraged to make more day-to-day choices and thus feel they had more responsibility for control over their lives. They began to decide such matters as what they ate, when their visitors could come, what movies they saw, and who could come to their rooms. A similar group in the same nursing home was told by the administrator how caring the nursing home was and how much the staff wanted to help, but these residents were given no opportunity to take more control over their lives. Eighteen months later, the residents who had been given responsibility and control were more alert and active, and said they were happier, than the residents who were only encouraged to feel that the staff would try to satisfy their needs. And the "responsible" or "self-control" group had significantly better improvement in their health than did the "dependent" group. Even more important was the finding that after 18 months only half as many nursing home residents in the "responsibility" group had died as in the "dependent" group (see Figure 17). Perceived control over one's environment, then, can literally be a matter of life or death.

Rodin's research shows that simply giving nursing home residents options for control can change their behavior and improve their health. To read further about health-care providers and older adults, see *Connecting Development to Life*.

**FIGURE 17**

### PERCEIVED CONTROL AND MORTALITY.

In the study by Rodin and Langer (1977), nursing home residents who were encouraged to feel more in control of their lives were more likely to be alive 18 months later than those who were treated as being more dependent on the nursing home staff. Source: Rodin, J., & Langer, E. J. "Long term effects of a control-relevant intervention with the institutionalized aged." *Journal of Personality and Social Psychology*, 35, 1977, 397–402.

## Review Connect Reflect

**LG3** Identify health problems in older adults and describe how they can be treated.

### Review

- What are some common health problems in older adults? What are the main causes of death in older adults?
- What characterizes substance abuse in late adulthood?
- How do exercise, nutrition, and weight influence development?
- What are some options and issues in the health treatment of older adults?

### Connect

- Older adults fare better when they are given more responsibility and control

in various aspects of their lives. At what other age stages is giving individuals more responsibility and control particularly important for their development?

### Reflect Your Own Personal Journey of Life

- What changes in your lifestyle now might help you age more successfully when you become an older adult?

## topical connections *looking forward*

In the next chapter, you will read about the benefits of engaging in challenging cognitive activities and staying cognitively fit in late adulthood. Links between the development of the brain and cognitive functioning will be examined. Aspects of work and retirement issues also will be explored. Mental health problems, including the dramatic increase in Alzheimer disease, will be discussed. And the roles of religion and spirituality in older adults' lives will be described.

## reach your learning goals

# Physical Development in Late Adulthood

### 1 Longevity

Life Expectancy and Life Span

The Young-Old and the Oldest-Old

Biological Theories of Aging

**LG1**

Characterize longevity and discuss the biological theories of aging.

- Life expectancy refers to the number of years that will probably be lived by an average person born in a particular year. Life span is the maximum number of years an individual can live. Life expectancy has dramatically increased; life span has not.
- An increasing number of individuals live to be 100 or older. Genetics, health, and coping well with stress can contribute to becoming a centenarian. On average, females live about six years longer than males do. The sex difference is likely due to biological and social factors.
- In terms of chronological age, the young-old have been described as being 65 to 84 years of age and the oldest-old as 85 years and older. Many experts on aging prefer to describe the young-old, old-old, and oldest-old in terms of functional age rather than chronological age. This view accounts for the fact that some 85-year-olds are more biologically and psychologically fit than some 65-year-olds. However, those 85 and older face significant problems, whereas those in their sixties and seventies are experiencing an increase in successful aging.
- The evolutionary theory of aging proposes that natural selection has not eliminated many harmful conditions and nonadaptive characteristics in older adults; thus, the benefits conferred by evolution decline with age because natural selection is linked to reproductive fitness.
- One recent view is that aging is caused by a combination of cellular maintenance requirements and evolutionary constraints. Among the key genetic and cellular processes that have been proposed to explain aging are those involving telomeres, free radicals, mitochondria, sirtuins, and the mTOR pathway. According to hormonal stress theory, aging in the body's hormonal system can lower resilience and increase the likelihood of disease.

## 2 The Course of Physical Development in Late Adulthood

The Aging Brain

Sleep

Physical Appearance and Movement

Sensory Development

The Circulatory and Respiratory Systems

Sexuality

LG2

Describe how a person's brain and body change in late adulthood.

- The brain loses weight and volume with age, and there is a general slowing of function in the central nervous system that begins in middle adulthood and increases in late adulthood. However, researchers have recently found that older adults can generate new neurons, and at least through the seventies, new dendrites.
- The aging brain retains considerable plasticity and adaptiveness. For example, it may compensate for losses in some regions of the brain by shifting responsibilities to other regions. A decrease in lateralization may reflect this kind of compensation, or it may reflect an age-related decline in the specialization of function.
- Approximately 50 percent of older adults complain of having difficulty sleeping. Poor sleep can result in earlier death and lower cognitive functioning. Many sleep problems among older adults are linked to health conditions.
- The most obvious signs of aging are wrinkled skin and age spots on the skin. People get shorter as they age, and their weight often decreases after age 60 because of loss of muscle. The movement of older adults slows across a wide range of movement tasks.
- Declines in visual acuity, color vision, and depth perception usually occur with age, especially after age 75. The yellowing of the eye's lens with age reduces color differentiation. The ability to see the periphery of a visual field also declines in older adults. Significant declines in visual functioning related to glare characterize adults 75 years and older and are prevalent among those 85 and older. Three diseases that can impair the vision of older adults are cataracts, glaucoma, and macular degeneration.
- Hearing decline can begin in middle age but usually does not become much of an impediment until late adulthood. Smell and taste can decline, although the decline is minimal in healthy older adults.
- Changes in touch sensitivity are associated with aging, although this does not present a problem for most older adults. Sensitivity to pain decreases in late adulthood. As with infants and children, perceptual motor coupling characterizes older adults; driving a vehicle is an example of this coupling.
- Cardiovascular disorders increase in late adulthood. Consistent high blood pressure should be treated to reduce the risk of stroke, heart attack, and kidney disease. Lung capacity does drop with age, but older adults can improve lung functioning with diaphragm-strengthening exercises.
- Aging in late adulthood does include some changes in sexual performance, more so for males than females. Nonetheless, there are no known age limits to sexual activity.

## 3 Health

Health Problems

Substance Use and Abuse

LG3

Identify health problems in older adults and describe how they can be treated.

- As we age, our probability of disease or illness increases. Chronic disorders are rare in early adulthood, increase in middle adulthood, and become more common in late adulthood. The most common chronic disorder in late adulthood is arthritis. Nearly three-fourths of older adults die of cancer, heart disease, or stroke.
- Osteoporosis is the main reason many older adults walk with a stoop; women are especially vulnerable to this condition. Accidents are usually more debilitating to older than to younger adults.
- The percentage of older adults who engage in binge drinking declines compared with earlier in adulthood, but moderate drinking of red wine can bring health benefits. Abuse of illicit and prescription drugs is a growing problem in the United States, although it is more difficult to detect in older adults than in younger adults.

Exercise, Nutrition,  
and Weight

- The physical benefits of exercise have been demonstrated in older adults. Aerobic exercise and weight lifting are both recommended for people who are physically capable of them. It is important for older adults to eat healthy foods and take appropriate vitamins.
- Current controversy involves whether overweight adults live longer than normal-weight adults. Being overweight is linked to health problems, and being obese predicts earlier death. Calorie restriction in animals can increase the animals' life span, but whether this works with humans is not known. In humans, there has been recent controversy about whether being overweight is associated with an increased or reduced mortality rate in older adults.
- Most nutritional experts recommend a well-balanced, low-fat diet for older adults but do not recommend an extremely low-calorie diet. Controversy surrounds the question of whether vitamin supplements—especially the antioxidants vitamin C, vitamin E, and beta-carotene—can slow the aging process and improve older adults' health. Recent research reviews concluded that taking antioxidant vitamin supplements does not reduce the risk of cancer and cardiovascular disease.
- Although only 3 percent of adults over 65 reside in nursing homes, 23 percent of adults 85 and over do. The quality of nursing homes varies enormously. Alternatives to nursing homes are being proposed. Simply giving nursing home residents options for control can change their behavior and improve their health. The attitudes of both the health-care provider and the older adult patient are important aspects of the older adult's health care. Too often health-care personnel share society's negative view of older adults.

# COGNITIVE DEVELOPMENT IN LATE ADULTHOOD

## chapter outline

### ① Cognitive Functioning in Older Adults

**Learning Goal 1** Describe the cognitive functioning of older adults  
Multidimensionality and Multidirectionality  
Education, Work, and Health  
Use It or Lose It  
Training Cognitive Skills  
Cognitive Neuroscience and Aging

### ② Language Development

**Learning Goal 2** Characterize changes in language skills in older adults

### ③ Work and Retirement

**Learning Goal 3** Discuss aging and adaptation to work and retirement  
Work  
Retirement in the United States and in Other Countries  
Adjustment to Retirement

### ④ Mental Health

**Learning Goal 4** Describe mental health problems in older adults  
Depression  
Dementia, Alzheimer Disease, and Other Afflictions

### ⑤ Religion and Spirituality

**Learning Goal 5** Explain the role of religion and spirituality in the lives of older adults

Helen Small with the author of your text, John Santrock, in his undergraduate course on life-span development at the University of Texas at Dallas in spring 2012. Helen returns each semester to talk with students in the class about cognitive aging. This past semester, I had to reschedule the date of the topic because Helen had other work commitments the day it was originally scheduled.

Courtesy of John Santrock

In 2010, 90-year-old Helen Small completed her master's degree at the University of Texas at Dallas (UT-Dallas). The topic of her master's degree research project was romantic relationships in older adults. Helen said she had interviewed only one individual who was older than she was at the time—a 92-year-old man.

I (your author, John Santrock) first met Helen when she took my undergraduate course in life-span development in 2006. After the first test, Helen stopped showing up and I wondered what had happened to her. It turns out that she had broken her shoulder when she tripped over a curb while hurrying to class. The next semester, she took my class again and did a great job in it, even though for the first several months she had to take notes with her left hand (she's right-handed) because of her lingering shoulder problem.

Helen grew up during the Great Depression and first went to college in 1938 at the University of Akron but attended for only one year. She got married and her marriage lasted 62 years. After her husband's death, Helen went back to college in 2002, first at Brookhaven Community College and then at UT-Dallas. When I interviewed her recently, she told me that she had promised her mother that she would finish college. Her most important advice for college students is this: "Finish college and be persistent. When you make a commitment, always see it through. Don't quit. Go after what you want in life."

Helen not only has been a cognitively fit older adult, she also has been physically fit. She regularly has worked out three times a week for about an hour each time—aerobically on a treadmill for about 30 minutes and then on six different weight machines.

What struck me most about Helen when she took my undergraduate course in life-span development was how appreciative she was of the opportunity to learn and how tenaciously she pursued studying and doing well in the course. Helen was quite popular with the younger students and was a terrific role model for them.

## topical connections *looking back*

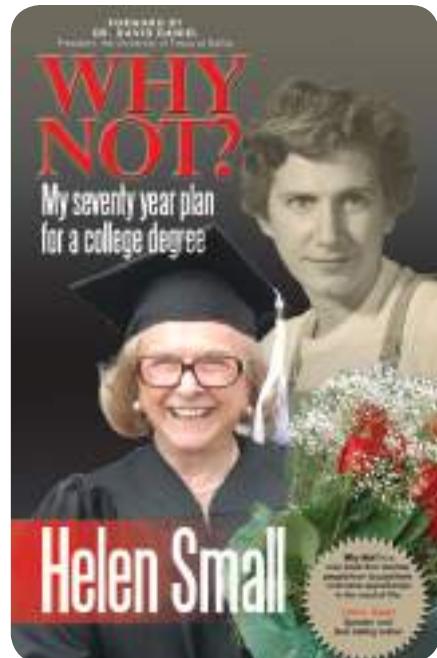

Most individuals reach the peak of their cognitive functioning in middle adulthood. However, some cognitive processes increase while others decline in middle age. For example, vocabulary peaks and speed of processing decreases in middle age. Expertise also typically increases during this age period. For many people, midlife is a time when individuals reflect and evaluate their current work and what they plan to do in the future. Many middle-aged adults increasingly examine life's meaning.

After her graduation, I asked her what she planned to do during the next few years and she responded, “I’ve got to figure out what I’m going to do with the rest of my life.” Helen has come each semester to my course in life-span development when we are discussing cognitive aging. She wows the class and has been an inspiration to all who come in contact with her.

What has Helen done recently to stay cognitively fit? She has worked as a public ambassador both for Dr. Denise Park’s Center for Vital Longevity at UT-Dallas and the Perot Science Museum. And Helen has been active in delivering meals through the Meals on Wheels organization that seeks to reduce hunger and social isolation in older adults. She also wrote her first book: *Why Not? My Seventy Year Plan for a College Degree* (Small, 2011). It’s a wonderful, motivating invitation to live your life fully and reach your potential no matter what your age. Following an amazing, fulfilling life, Helen Small passed away in 2017 at the age of 97.

## preview

Helen Small has led a very active cognitive life as an older adult. Just how well older adults can and do function cognitively is an important question we will explore in this chapter. We also will examine aspects of language development, work and retirement, mental health, and religion.

Helen Small published her first book, *Why Not? My Seventy Year Plan for a College Degree*, in 2011 at the age of 91.  
Courtesy of Helen Small

### 1 Cognitive Functioning in Older Adults

**LG1** Describe the cognitive functioning of older adults.

Multidimensionality  
and Multidirectionality

Education, Work,  
and Health

Use It or Lose It

Training Cognitive  
Skills

Cognitive Neuroscience  
and Aging

At age 76, Anna Mary Robertson Moses, better known as Grandma Moses, took up painting and became internationally famous, staging 15 one-woman shows throughout Europe. At age 89, Arthur Rubinstein gave one of his best performances at New York’s Carnegie Hall. When Pablo Casals was 95, a reporter asked him, “Mr. Casals, you are the greatest cellist who ever lived. Why do you still practice six hours a day?” Mr. Casals replied, “Because I feel like I am making progress” (Canfield & Hansen, 1995).

#### MULTIDIMENSIONALITY AND MULTIDIRECTIONALITY

In thinking about the nature of cognitive change in adulthood, it is important to keep in mind that cognition is a multidimensional concept (Kinugawa, 2019; Silverman & Schmeidler, 2018; Zammit & others, 2018). It is also important to realize that although some dimensions of cognition might decline as we age, others might remain stable or even improve.

**Cognitive Mechanics and Cognitive Pragmatics** Paul Baltes (2003; Baltes, Lindenberger, & Staudinger, 2006) clarified the distinction between those aspects of the aging mind that show decline and those that remain stable or even improve:

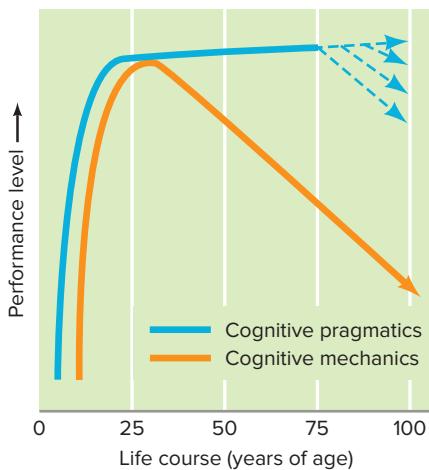

- **Cognitive mechanics** are the “hardware” of the mind and reflect the neurophysiological architecture of the brain that was developed through evolution. Cognitive mechanics consist of these components: speed and accuracy of the processes involved in sensory input, attention, visual and motor memory, discrimination, comparison, and categorization. Because of the strong influence of biology, heredity, and health on cognitive mechanics, this aspect of thinking is likely to decline with age. Some researchers conclude that the decline in cognitive mechanics may begin as soon as early midlife (Salthouse, 2013a, b).

#### developmental connection

##### Intelligence

Fluid intelligence is the ability to reason abstractly; crystallized intelligence is an individual’s accumulated information and verbal skills. Connect to “Physical and Cognitive Development in Middle Adulthood.”

**cognitive mechanics** The “hardware” of the mind, reflecting the neurophysiological architecture of the brain. Cognitive mechanics involve the speed and accuracy of the processes involving sensory input, visual and motor memory, discrimination, comparison, and categorization.

**FIGURE 1**  
**THEORIZED AGE CHANGES IN COGNITIVE MECHANICS AND**

**COGNITIVE PRAGMATICS.** Baltes argues that cognitive mechanics decline during aging, whereas cognitive pragmatics do not decline for many people until they become very old. Cognitive mechanics have a biological/genetic foundation; cognitive pragmatics have an experiential/cultural foundation. The broken lines from 75 to 100 years of age indicate possible individual variations in cognitive pragmatics.

- **Cognitive pragmatics** are the culture-based “software programs” of the mind. Cognitive pragmatics include reading and writing skills, language comprehension, educational qualifications, professional skills, and also the self-understanding and life skills that help us to master or cope with challenges. Because of the strong influence of culture on cognitive pragmatics, it is possible for them to continue improving into old age. Thus, although cognitive mechanics may decline in old age, cognitive pragmatics may actually improve, at least until individuals become very old (see Figure 1).

The distinction between cognitive mechanics and cognitive pragmatics is similar to the one between fluid (mechanics) and crystallized (pragmatics) intelligence. Indeed, the similarity is so strong that some experts now describe cognitive aging patterns in terms of *fluid mechanics* and *crystallized pragmatics* (Lovden & Lindenberger, 2007).

What factors are most likely to contribute to the decline in fluid mechanics in late adulthood? Among the most likely candidates are declines in processing speed and working memory capacity, and reduced effectiveness in suppressing irrelevant information (inhibition) (Lovden & Lindenberger, 2007).

Now that we have examined the distinction between fluid mechanics and crystallized pragmatics, let’s explore some of the more specific cognitive processes that reflect these two general domains, beginning with speed of processing.

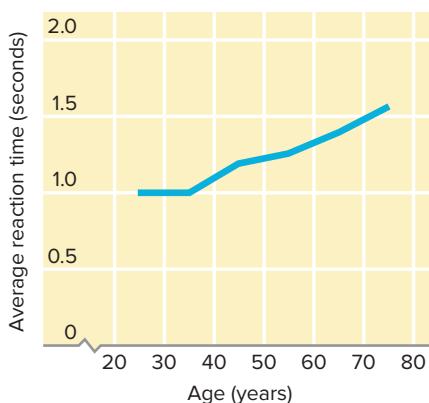

**Speed of Processing** It is now well accepted that the speed of processing information declines in late adulthood (Anblagan & others, 2018; Baudouin, Isingrini, & Vanneste, 2018; Gilsoul & others, 2018; McInerney & Suhr, 2016; Ross & others, 2016; Salthouse, 2012, 2017; Sanders & others, 2017). Figure 2 illustrates this decline through the results of a study that measured reaction times in adults. A meta-analysis confirmed that processing speed increases through the childhood and adolescent years, begins to decline at some point during the latter part of early adulthood, and then continues to decline through the remainder of the adult years (Verhaeghen, 2013).

Although speed of processing information slows down in late adulthood, there is considerable individual variation in this ability. These variations in thinking speed appear to be correlated with physical aspects of aging. A recent study found that slow processing speed predicted an increase in older adults’ falls one year later (Davis & others, 2017). Accumulated knowledge may compensate to some degree for slower processing speed in older adults.

Researchers have found that a slowing of processing speed at baseline is linked to the emergence of dementia over the next six years (Welmer & others, 2014). Further, a German study of 50- to 90-year-olds found that those who were tested more recently had a faster processing speed than their counterparts (at the same age) who were tested six years previously (Steiber, 2015). And in a large-scale study of middle-aged and older adults, out of 65 mortality risk factors, processing speed and health status were among the best predictors of living longer (Aichele, Rabbitt, & Ghisletta, 2016).

The decline in processing speed in older adults is likely due to a decline in functioning of the brain and central nervous system (Anblagan & others, 2018; Demnitz & others, 2017; Hedden & others, 2016). In a research meta-analysis, age-related losses in processing speed were explained by a decline in neural connectivity or indirectly through changes in dopamine, or both (Verhaeghen, 2013). Another study revealed that age-related slowing in processing speed was linked to a breakdown in myelin in the brain (Lu & others, 2013). Research suggests that processing speed is an important indicator of the ability of older adults to continue to safely drive a vehicle (Edwards & others, 2010; Ross & others, 2016). An analysis of driving accidents revealed that approximately 50 percent of accidents in people over 50 years of age occur at intersections, compared with only about 23 percent for those under 50 years of age (Michel, 2014). Intersections with yellow traffic lights posed difficulty for older adults, but when given advance warning 1.5 seconds before the traffic light was about to change from green to yellow, they were less likely to have an accident. A recent study indicated that impaired visual processing speed predicted an increase in vehicle crashes in older adults (Huisingsh & others, 2017). And another recent study revealed that cognitive speed of processing training was linked to driving frequency and prolonged driving across a five-year period in older adults (Ross & others, 2016).

Recent research has included an effort to improve older adults’ processing speed through exercise interventions. For example, a recent experimental study found that high-intensity

**FIGURE 2**  
**THE RELATION OF AGE TO REACTION TIME.**

**TIME.** In one study, the average reaction time began to slow in the forties, and this decline accelerated in the sixties and seventies (Salthouse, 1994). The task used to assess reaction time required individuals to match numbers with symbols on a computer screen.

**cognitive pragmatics** The culture-based “software programs” of the mind. Cognitive pragmatics include reading and writing skills, language comprehension, educational qualifications, professional skills, and also knowledge about the self and life skills that help us to master or cope with life.

aerobic training was more effective than moderate-intensity aerobic training or resistance training in improving older adults' processing speed (Coetsee & Terblanche, 2017). And in a recent study of older adults, playing processing speed games for five sessions a week over four weeks improved their processing speed (Nouchi & others, 2016).

**Attention** Changes in attention are important aspects of cognitive aging (Bechi Gabrielli & others, 2018; Hoyer, 2015; Oren & others, 2018). In many contexts older adults may not be able to focus on relevant information as effectively as younger adults can (Deroche & others, 2016; Fountain-Zaragoza & Prakash, 2017; Gilsoul & others, 2018; Williams & others, 2017).

Researchers have found that older adults are less able to ignore distracting information than younger adults, and this distractibility becomes more pronounced as attentional demands increase (Mund, Bell, & Buchner, 2010; Ziegler, Janowich, & Gazzaley, 2018). Research indicates that the greater distractibility of older adults is associated with less effective functioning in neural networks running through the frontal and parietal lobes of the brain, which are involved in cognitive control (Campbell & others, 2012). Also, a research review concluded that more active and physically fit older adults are better able to allocate attention when interacting with the environment (Gomez-Pinilla & Hillman, 2013). Another study revealed that older adults who participated in 20 one-hour video game training sessions with a commercially available program (Lumosity) showed a significant reduction in distraction and increased alertness (Mayas & others, 2014). The Lumosity program sessions focus on problem solving, mental calculation, working memory, and attention. And in a recent experimental study, yoga practice that included postures, breathing, and meditation improved the attention and information processing of older adults (Gothe, Kramer, & McAuley, 2017). Also, another recent study found that when older adults regularly engaged in mindfulness meditation their goal-directed attention improved (Malinowski & others, 2017).

The chapter on "Physical and Cognitive Development in Early Childhood" described two types of attention—sustained and executive. Here we will discuss those two types of attention in older adults as well as two other types of attention: selective and divided attention.

- **Selective attention** involves focusing on a specific aspect of experience that is relevant while ignoring others that are irrelevant. An example of selective attention is the ability to focus on one voice among many in a crowded room or a noisy restaurant. Another is making a decision about which stimuli to attend to when making a left turn at an intersection. Generally, older adults are less adept at selective attention than younger adults are (Ben-David & others, 2014; Gilsoul & others, 2018; Zanto & Gazzaley, 2017). Recent research indicates that older adults' auditory selective attention with visual distraction is especially impaired (Van Gerven & Guerreiro, 2016). Also, in one study, 10 weeks of training in speed of processing improved the selective attention of older adults (O'Brien & others, 2013).
- **Divided attention** involves concentrating on more than one activity at the same time. When the two competing tasks are reasonably easy, age differences among adults are minimal or nonexistent. However, the more difficult the competing tasks are, the less effectively older adults divide attention than younger adults (Bucur & Madden, 2007).
- **Sustained attention** is focused and extended engagement with an object, task, event, or some other aspect of the environment. Sometimes sustained attention is referred to as *vigilance*. On tests of simple vigilance and sustained attention, older adults usually perform as well as younger adults. However, on complex vigilance tasks, older adults' performance usually drops (Bucur & Madden, 2007). And a study of older adults found that the greater the variability in their sustained attention (vigilance), the more likely they were to experience falls (O'Halloran & others, 2011).

It is possible, however, that older adults' experience and wisdom might offset some of their declines in vigilance. For example, consider how frequently young people focus intently on their smartphone rather than looking at traffic when crossing a dangerous intersection.

- **Executive attention** involves planning actions, allocating attention to goals, detecting and compensating for errors, monitoring progress on tasks, and dealing with novel or difficult circumstances. One study found that older adults had deficiencies in executive attention (Mahoney & others, 2010). In this study, a lower level of executive attention in older adults was linked to low blood pressure, which likely is related to reduced blood flow to the brain's frontal lobes.

What are some developmental changes in attention in late adulthood?

### developmental connection

#### Attention

Young children make progress in many aspects of attention, including sustained attention and executive attention. Connect to "Physical and Cognitive Development in Early Childhood."

**selective attention** Focusing on a specific aspect of experience that is relevant while ignoring others that are irrelevant.

**divided attention** Concentrating on more than one activity at the same time.

**sustained attention** Focused and extended engagement with an object, task, event, or other aspect of the environment.

**executive attention** Aspects of thinking that include planning actions, allocating attention to goals, detecting and compensating for errors, monitoring progress on tasks, and dealing with novel or difficult circumstances.

**Memory** The main dimensions of memory and aging that have been studied include explicit and implicit memory, episodic memory, semantic memory, cognitive resources (such as working memory and perceptual speed), source memory, prospective memory, and noncognitive influences such as health, education, and socioeconomic factors.

**Explicit and Implicit Memory** Researchers have found that aging is linked with a decline in explicit memory (Lustig & Lin, 2016; Reuter-Lorenz & Lustig, 2017). **Explicit memory** is memory of facts and experiences that individuals consciously know and can state. Explicit memory also is sometimes called declarative memory. Examples of explicit memory include being at a grocery store and remembering what you wanted to buy, being able to name the capital of Illinois, or recounting the events in a movie you have seen. **Implicit memory** is memory without conscious recollection; it involves skills and routine procedures that are performed automatically. Examples of implicit memory include driving a car, swinging a golf club, or typing on a computer keyboard without having to consciously think about how to perform these tasks.

Implicit memory is less likely to be adversely affected by aging than explicit memory is (Nyberg & others, 2012). Thus, older adults are more likely to forget what items they wanted to buy at a grocery store (unless they write them down on a list and take it with them) than they are to forget how to drive a car. Their perceptual speed might be slower in driving a car, but they remember how to do it.

**Episodic Memory and Semantic Memory** Episodic and semantic memory are viewed as forms of explicit memory. **Episodic memory** is the retention of information about the details of life's happenings. For example, what was the color of the walls in your bedroom when you were a child, what was your first date like, what were you doing when you heard that airplanes had struck the World Trade Center, and what did you eat for breakfast this morning?

Younger adults have better episodic memory than older adults have, both for real and imagined events (Allen & others, 2018; Despres & others, 2017; Siegel & Castel, 2018; Wang & Cabeza, 2017). A study of 18- to 94-year-olds revealed that increased age was linked to increased difficulty in retrieving episodic information, facts, and events (Siedlecki, 2007). Also, older adults think that they can remember older events better than more recent events, typically reporting that they can remember what happened to them years ago but can't remember what they did yesterday. However, researchers consistently have found that, contrary to such self-reports, in older adults the older the memory, the less accurate it is. This has been documented in studies of memory for high school classmates, foreign languages learned in school over the life span, names of grade school teachers, and autobiographical facts kept in diaries (Smith, 1996). A recent study found that episodic memory performance predicted which individuals would develop dementia 10 years prior to the clinical diagnosis of the disease (Boraxbekk & others, 2015). In a recent study, a mindfulness training program was effective in improving episodic memory recall in older adults (Banducci & others, 2017).

**Semantic memory** is a person's knowledge about the world. It includes a person's fields of expertise, such as knowledge of chess for a skilled chess player; general academic knowledge of the sort learned in school, such as knowledge of geometry; and "everyday knowledge" about the meanings of words, the names of famous individuals, the significance of important places, and common things such as what day is Valentine's Day. Semantic memory appears to be independent of an individual's personal identity with the past. For example, you can access a fact—such as "Lima is the capital of Peru"—and not have the foggiest idea of when and where you learned it.

Does semantic memory decline with age? Among the tasks that researchers often use to assess semantic memory are those involving vocabulary, general knowledge, and word identification (Miotto & others, 2013). Older adults do often take longer to retrieve semantic information, but usually they can ultimately retrieve it. However, the ability to retrieve very specific information (such as names) usually declines in older adults (Hoffman & Morcom, 2018; Luo & Craik, 2008). For the most part, episodic memory declines more than semantic memory in older adults (Allen & others, 2018; Lustig & Lin, 2016; Reuter-Lorenz & Lustig, 2017; Siegel & Castel, 2018).

Although many aspects of semantic memory are reasonably well preserved in late adulthood, a common memory problem for older adults is the *tip-of-the-tongue (TOT) phenomenon*,

**explicit memory** Memory of facts and experiences that individuals consciously know and can state.

**implicit memory** Memory without conscious recollection; involves skills and routine procedures that are automatically performed.

**episodic memory** The retention of information about the details of life's happenings.

**semantic memory** A person's knowledge about the world—including one's fields of expertise, general academic knowledge of the sort learned in school, and "everyday knowledge."

in which individuals can't quite retrieve familiar information but have the feeling that they should be able to retrieve it (Salthouse & Mandell, 2013). Researchers have found that older adults are more likely to experience TOT states than younger adults are (Huijbers & others, 2017). A study of older adults found that the most commonly reported errors in memory over the last 24 hours were those involving tip-of-the-tongue (Ossher, Flegal, & Lustig, 2013).

**Cognitive Resources: Working Memory and Perceptual Speed** One view of memory suggests that a limited amount of cognitive resources can be devoted to any cognitive task. Two important cognitive resource mechanisms are working memory and perceptual speed (Baddeley, 2015, 2017, 2018a, b; McInerney & Suhr, 2016). Recall that *working memory* is closely linked to short-term memory but places more emphasis on memory as a place for mental work. Working memory is like a mental "workbench" that allows children and adults to manipulate and assemble information when making decisions, solving problems, and comprehending written and spoken language (Baddeley, 2007, 2010, 2012, 2015, 2017, 2018a, b). Researchers have found declines in working memory during late adulthood (Dai, Thomas, & Taylor, 2018; Kilic, Sayali, & Oztekin, 2017; Nissim & others, 2017). One study revealed that working memory continued to decline from 65 to 89 years of age (Elliott & others, 2011).

Explanations of the decline in working memory in older adults often focus on their less efficient inhibition (preventing irrelevant information from entering working memory) and their increased distractibility (Lopez-Higes & others, 2018; Lustig & Lin, 2016; Reuter-Lorenz & Lustig, 2017). Is there plasticity in the working memory of older adults? Researchers have found that older adults' working memory can be improved through training (Cantarella & others, 2017; Reuter-Lorenz & Lustig, 2017). And a research meta-analysis concluded that training on working memory can improve fluid intelligence (Au & others, 2015). Also, an experimental study revealed that moderate exercise resulted in faster reaction times on a working memory task in older adults (Hogan, Mata, & Carstensen, 2013). Further, in a recent study, aerobic endurance was linked to better working memory in older adults (Zettel-Watson & others, 2017). In addition, a recent study revealed that imagery strategy training improved the working memory of older adults (Borella & others, 2017). Thus, there appears to be some plasticity in the working memory of older adults (Oh & others, 2018). However, a recent study of young, middle-aged, and older adults found that all age groups' working memory improved with working memory training, but the improvement was less in older adults than in young adults (Rhodes & Katz, 2017).

Perceptual speed is a cognitive resource that involves the ability to perform simple perceptual-motor tasks such as deciding whether pairs of two-digit or two-letter strings are the same or different or determining the time required to step on the brakes when the car directly ahead stops. Perceptual speed shows considerable decline in late adulthood and is strongly linked to declines in working memory (Hoogendam & others, 2014; Salthouse, 2017; Wilson & others, 2018). One study revealed that age-related slowing in processing speed was linked to a breakdown in myelin in the brain (Lu & others, 2013). And in another study of older adults, slower processing speed was associated with unsafe driving acts (Hotta & others, 2018). However, another study found that 10 hours of training targeted toward enhancing visual speed of processing was effective in improving older adults' speed of processing, attention, and executive function (Wolinsky & others, 2013).

**Source Memory** **Source memory** is the ability to remember where one learned something (Ward, 2018). Failures of source memory increase with age in the adult years and they can create awkward situations, as when an older adult forgets who told a joke and retells it to the source (El Haj, Fasotti, & Allain, 2015; Meusel & others, 2017). One study revealed that self-referenced encoding improved the source memory of older adults (Leshikar & Duarte, 2014).

Lynn Hasher (2003, p. 1301) argues that age differences in performance are substantial in many tests of memory, such as source memory, when individuals are asked "for a piece of information that just doesn't matter much. But if you ask for information that is important, old people do every bit as well as young adults . . . young people have mental resources to burn. As people get older, they get more selective in how they use their resources."

**Prospective Memory** **Prospective memory** involves remembering to do something in the future, such as remembering to take your medicine or remembering to do an errand (Ballhausen & others, 2017; Ihle, Ghisletta, & Kliegel, 2017; Insel & others, 2016; Simard & others, 2018; Sullivan & others, 2018). Also, prospective memory has been referred to as remembering to

This older woman has forgotten where she put the keys to her car. *What type of memory is involved in this situation?*

©Clarissa Leahy/The Image Bank/Getty Images

**source memory** The ability to remember where one learned something.

**prospective memory** Remembering to do something in the future.

Prospective memory involves remembering to do something in the future. This woman is keeping track of what she plans to buy when she goes to a grocery store the next day.

©DAJ/Getty Images

remember (Kliegel & others, 2016). In one study, prospective memory played an important role in older adults' successful management of the medications they needed to take (Woods & others, 2014). Some researchers have found a decline in prospective memory with age (Kennedy & others, 2015; Smith & Hunt, 2014). However, a number of studies show that whether there is a decline depends on factors such as the nature of the task, what is being assessed, and the context of the assessment (Mullet & others, 2013; Scullin, Bugg, & McDaniel, 2012). For example, age-related deficits occur more often in prospective memory tasks that are time-based (such as remembering to call someone next Friday) than in those that are event-based (remembering to tell your friend to read a particular book the next time you see her). Further, declines in prospective memory occur more often in laboratories than in real-life settings (Bisiacchi, Tarantino, & Ciccola, 2008). Indeed, in some real-life settings, such as keeping appointments, older adults' prospective memory is better than younger adults' (Luo & Craik, 2008). And a recent study found that planning strategies were associated with older adults' prospective memory (Wolff & others, 2016).

**Conclusions About Memory and Aging** Most, but not all, aspects of memory decline during late adulthood (Reuter-Lorenz & Lustig, 2017). The decline occurs primarily in explicit, episodic, and working memory, not in semantic memory or implicit memory (Allen & others, 2018; Lopez-Higes & others, 2018). A decline in perceptual speed is associated with memory decline (Salthouse, 2017; Wilson & others, 2018). Successful aging does not mean eliminating memory decline altogether, but it does mean reducing the decline and adapting to it.

Older adults can use certain strategies to reduce memory decline (Bottiroli & others, 2017; Hinault, Lemaire, & Touron, 2017; Frankenmolen & others, 2018; Karthaus, Wascher, & Getzmann, 2018; Kuhlmann & Touron, 2017). In recent research, strategies involving elaboration and self-referential processing were effective in improving the memory of older adults, actually helping older adults' memory more than younger adults' memory (Trelle, Henson, & Simons, 2015). However, a recent analysis concluded that older adults are slower than younger adults in shifting from an initial effortful strategy to using a faster and easier memory-based strategy (Touron, 2015). In a recent study, using compensation strategies (for example, managing appointments by routinely writing them on a calendar) was associated with higher levels of independence in everyday function in cognitively normal older adults and older adults with mild cognitive impairment (Tomaszewski Farias & others, 2018).

## developmental connection

### Cognitive Processes

Executive function is increasingly recognized as an important facet of cognitive development. Connect to "Physical and Cognitive Development in Early Childhood," "Physical and Cognitive Development in Middle and Late Adulthood," and "Physical and Cognitive Development in Adolescence."

**Executive Function** Recall that *executive function* is an umbrella-like concept that consists of a number of higher-level cognitive processes linked to the development of the brain's prefrontal cortex (Reuter-Lorenz, Festini, & Jantz, 2016). Executive function involves managing one's thoughts to engage in goal-directed behavior and to exercise self-control.

How does executive function change in late adulthood? The prefrontal cortex is one area of the brain that especially shrinks with aging, and recent research has linked this shrinkage with a decrease in working memory and other cognitive activities in older adults (Reuter-Lorenz & Lustig, 2017). One study found that dysregulation of signaling by the neurotransmitter GABA may play a role in impaired working memory in older adults (Banuelos & others, 2014).

Executive function skills decline in older adults (Gaillardin & Baudry, 2018; Lin & others, 2017). Aspects of working memory that especially decline in older adults involve (1) updating memory representations that are relevant for the task at hand and (2) replacing old, no longer relevant information (Friedman & others, 2008). Older adults also are less effective at engaging in cognitive control than when they were younger (Lin & others, 2017; Zammit & others, 2018). For example, in terms of cognitive flexibility, older adults don't perform as well as younger adults at switching back and forth between tasks or mental sets (Chiu & others, 2018). And in terms of cognitive inhibition, older adults are less effective than younger adults at inhibiting dominant or automatic responses (Lopez-Higes & others, 2018; Reuter-Lorenz, Festini, & Jantz, 2016).

Although aspects of executive function tend to decline in late adulthood, there is considerable variability in executive function among older adults. For example, some older adults have a better working memory and are more cognitively flexible than other older adults (Kayama & others, 2014). Further, there is increasing research evidence that aerobic exercise improves executive function in older adults (Eggenberger & others, 2015). For example, a recent study of older adults revealed that across a 10-year period physically active women experienced less decline in executive function than sedentary women (Hamer, Muniz Terrera, & Demakakos,

2018). And in another study, more physically fit older adults had greater cognitive flexibility than their less physically fit counterparts (Berryman & others, 2013). Also, in a research meta-analysis, tai chi participation was associated with better executive function in older adults (Wayne & others, 2014).

Executive function increasingly is thought to be involved not only in cognitive performance but also in health, emotion regulation, adaptation to life's challenges, motivation, and social functioning (Forte & others, 2013). Research on these aspects of executive function has only recently begun. In one study, deficits in executive function but not memory predicted a higher risk of coronary heart disease and stroke three years later in older adults (Rostamian & others, 2015).

Some critics argue that not much benefit is derived from placing various cognitive processes under the broader concept of executive function. Although we have described a number of components of executive function here—working memory, cognitive inhibition, cognitive flexibility, and so on—a consensus has not been reached on what the components are, how they are connected, and how they develop. That said, the concept of executive function is not likely to go away any time soon, and further research, especially meta-analyses, should provide a clearer picture of executive function and how it develops through the life span (Luszcz, 2011).

**Decision Making** Despite declines in many aspects of memory, such as working memory and long-term memory, many older adults preserve decision-making skills reasonably well (Healey & Hasher, 2009; You & others, 2018). However, some researchers have found negative changes in decision making in older adults (Eppinger & others, 2013). One study revealed that compared with younger adults, older adults were far more inconsistent in their choices (Tymula & others, 2013). Also, in some cases, age-related decreases in memory will impair decision making (Brand & Markowitsch, 2010). One study revealed that a reduction in effective decision making in risky situations during late adulthood was linked to declines in memory and processing speed (Henninger, Madden, & Huettel, 2010). Also, in a recent study, younger adults made better decisions than older adults in unfamiliar domains, but not in familiar domains (Wayde, Black, & Gilpin, 2017). Further, older adults often perform well when decision making is not constrained by time pressures, when the decision is meaningful for them, and when the decisions do not involve high risks (Boyle & others, 2012; Yoon, Cole, & Lee, 2009).

**Metacognition** By middle age, adults have accumulated a great deal of metacognitive knowledge. They can draw on this metacognitive knowledge to help them combat a decline in memory skills. For example, they are likely to understand that they need to have good organizational skills and reminders to help combat the decline in memory skills they face.

Older adults tend to overestimate the memory problems they experience on a daily basis. They seem to be more aware of their memory failures than younger adults and become more anxious about minor forgetfulness than younger adults do (Hoyer & Roodin, 2009). Researchers have found that in general older adults are as accurate as younger adults in monitoring the encoding and retrieval of information (McGillivray & Castel, 2017), as well as detecting errors when asked to proofread passages and judging their own performance (Hargis & others, 2017). However, some aspects of monitoring information, such as source memory (discussed earlier in the chapter), decline in older adults (Souchay & others, 2007).

**Mindfulness** Recall that *mindfulness* involves being alert, mentally present, and cognitively flexible while going through life's everyday activities and tasks. Recently, there has been growing interest in mindfulness training with older adults, which has mainly focused on meditation (Fountain-Zaragoza & Prakash, 2017). Some, but not all, studies have shown that mindfulness training improves older adults' cognitive functioning (Fountain-Zaragoza & Prakas, 2017; Kovach & others, 2018; Oken & others, 2018). In one study, a mindfulness-based stress reduction program involving meditation improved older adults' memory and inhibitory control (Lenze & others, 2014).

**Wisdom** Does wisdom, like good wine, improve with age? What is this thing we call "wisdom"? A research review found 24 definitions of wisdom, although there was significant overlap in the definitions (Bangen, Meeks, & Jest, 2013). In this review, the following subcomponents of wisdom were commonly cited: knowledge of life, prosocial values, self-understanding, acknowledgment of uncertainty, emotional balance, tolerance, openness, spirituality, and sense of humor.

Older adults might not be as quick with their thoughts or behavior as younger people, but wisdom may be an entirely different matter. This older woman shares the wisdom of her experience with a classroom of children.

*How is wisdom described by life-span developmentalists?*

©Elizabeth Crews

Thus, while there is still some disagreement regarding how wisdom should be defined, the following definition of wisdom has been used by leading expert Paul Baltes and his colleagues (Baltes & Kunzmann, 2007; Baltes & Smith, 2008): **Wisdom** is expert knowledge about the practical aspects of life that permits excellent judgment about important matters. This practical knowledge involves exceptional insight into human development and life matters, good judgment, and an understanding of how to cope with difficult life problems.

Thus, wisdom, more than standard conceptions of intelligence, focuses on life's pragmatic concerns and human conditions (Kuntzmann, 2019; Sternberg, 2018i; Sternberg & Glueck, 2018; Sternberg & Hagen, 2018). A recent study found that self-reflective exploratory processing of difficult life experiences (meaning-making and personal growth) was linked to a higher level of wisdom (Westrate & Gluck, 2017).

In regard to wisdom, research by Baltes and his colleagues (Baltes & Kunzmann, 2007; Baltes & Smith, 2008) yielded the following findings:

- High levels of wisdom are rare. Few people, including older adults, attain a high level of wisdom. That only a small percentage of adults show wisdom supports the contention that it requires experience, practice, or complex skills.
- The time frame of late adolescence and early adulthood is the main age window for wisdom to emerge (Staudinger & Dorner, 2007; Staudinger & Gluck, 2011). No further advances in wisdom have been found for middle-aged and older adults beyond the level they attained as young adults.
- Factors other than age are critical for wisdom to develop to a high level. For example, certain life experiences, such as being trained and working in a field concerned with difficult life problems and having wisdom-enhancing mentors, contribute to higher levels of wisdom. Also, people higher in wisdom have values that are more likely to consider the welfare of others than to focus solely on their own happiness.
- Personality-related factors, such as openness to experience, generativity, and creativity, are better predictors of wisdom than cognitive factors such as intelligence.

## EDUCATION, WORK, AND HEALTH

Education, work, and health are three important influences on the cognitive functioning of older adults (Calero, 2019; Walker, 2019). They are also three of the most important factors involved in understanding why cohort effects need to be taken into account in studying the cognitive functioning of older adults. Indeed, cohort effects are very important considerations in the study of cognitive aging (Schaie, 2013, 2016a). For example, a recent study found that older adults assessed in 2013–2014 engaged in a higher level of abstract reasoning than their counterparts who had been assessed two decades earlier (Gerstorf & others, 2015). And a recent study of older adults in 10 European countries revealed improved memory between 2004 and 2013, with the changes more positive for older adults who had decreases in cardiovascular disease and increases in exercise and educational achievement (Hessel & others, 2018).

**Education** Successive generations in America's twentieth century were better educated, and this trend continues in the twenty-first century (Schaie, 2013, 2016a). Not only were today's older adults more likely to go to college when they were young adults than were their parents or grandparents, but more older adults are returning to college today to further their education than in past generations. Educational experiences are positively correlated with scores on intelligence tests and information-processing tasks, such as memory exercises (Steffener & others, 2014). One study revealed that older adults with less education had lower cognitive abilities than those with more education (Lachman & others, 2010). However, for older adults with less education, frequently engaging in cognitive activities improved their episodic memory. Another study found that older adults with a higher level of education had better cognitive functioning (Rapp & others, 2013).

**Work** Successive generations have also had work experiences that included a stronger emphasis on cognitively oriented labor. Our great-grandfathers and grandfathers were more likely to be manual laborers than were our fathers, who are more likely to be involved in cognitively oriented occupations. As the industrial society continues to be replaced by the information society, younger generations will have more experience in jobs that require considerable

**wisdom** Expert knowledge about the practical aspects of life that permits excellent judgment about important matters.

cognitive investment. The increased emphasis on complex information processing in jobs likely enhances an individual's intellectual abilities (Lovden, Backman, & Lindenberger, 2017).

Researchers have found that when older adults engage in complex working tasks and challenging daily work activities, their cognitive functioning shows less age-related decrease (Fisher & others, 2017; Lovden, Backman, & Lindenberger, 2017). For example, in a recent Australian study, older adults who had retired from occupations that involved higher complexity maintained their cognitive advantage over their counterparts whose occupations had involved lower complexity (Lane & others, 2017). Also, a study of middle-aged and older adults found that employment gaps involving unemployment or sickness were associated with a higher risk of cognitive impairment (Leist & others, 2013). Further, researchers have found that working in an occupation with a high level of mental demands is linked to higher levels of cognitive functioning before retirement and a slower rate of cognitive decline after retirement (Fisher & others, 2014). And in another recent study of older adults working in low-complexity jobs, experiencing novelty in their work (assessed through recurrent work-task changes) was linked with better processing speed and working memory (Oltmanns & others, 2017).

**Health** Successive generations have also been healthier in late adulthood as better treatments for a variety of illnesses (such as hypertension) have been developed. Many of these illnesses, such as stroke, heart disease, and diabetes have a negative impact on intellectual performance (Li, Huang, & Gao, 2017; Loprinzi, Crush, & Joyner, 2017). Hypertension has been linked to lower cognitive performance in a number of studies, not only in older adults but also in young and middle-aged adults (Kherada, Heimowitz, & Rosendorff, 2015; van der Flier & others, 2018). Also, researchers have found that cardiovascular disease is associated with cognitive decline in older adults (Hagenaars & others, 2018; Hessel & others, 2018). Further, in a recent review of older adults with type 2 diabetes, it was concluded that the disease was linked with an increase in cognitive impairment (Riederer & others, 2017). In addition, a recent study of the oldest-old Chinese revealed that early-stage chronic kidney disease was associated with cognitive decline (Bai & others, 2017). And, as we will see later in this chapter, Alzheimer disease has a devastating effect on older adults' physical and cognitive functioning (Park & Farrell, 2016). Researchers also have found age-related cognitive decline in adults with mood disorders such as depression (Farioli-Vecchioli & others, 2018; Bourassa & others, 2017). Thus, some of the decline in intellectual performance found in older adults is likely due to health-related factors rather than to age per se (Drew & others, 2017; Harrison & others, 2017; Koyanagi & others, 2018; Lin & others, 2017).

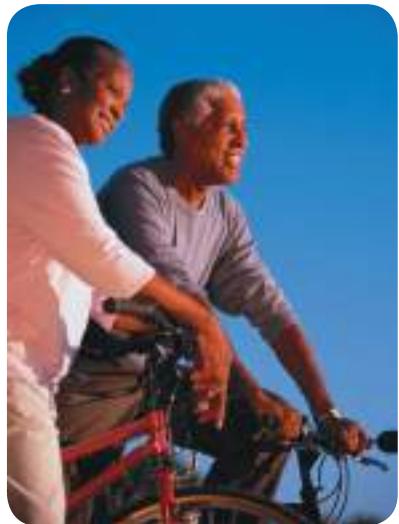

A number of research studies have found that exercise is linked to improved cognitive functioning in older adults (Erickson & Liu-Ambrose, 2016; Gill & others, 2016; Kennedy & others, 2017; Macpherson & others, 2017; Moreira & others, 2018; Strandberg, 2019; Walker, 2019). Walking or any other aerobic exercise appears to get blood and oxygen pumping to the brain, which can help people think more clearly.

Dietary patterns also are linked to cognitive functioning in older adults (Perkis & Vandewoude, 2019). For example, a recent research review concluded that multinutrient approaches using the Mediterranean diet are linked to a lower risk of cognitive impairment (Abatecola, Russo, & Barbieri, 2018).

A final aspect of health that is related to cognitive functioning in older adults is *terminal decline*. This concept emphasizes that changes in cognitive functioning may be linked more to distance from death or cognition-related pathology than to distance from birth (Bendayan & others, 2017; Gerstorf & Ram, 2015; Wilson & others, 2018; Zaslavsky & others, 2015). In one study, on average, a faster rate of cognitive decline occurred about 7.7 years prior to death and varied across individuals (Muniz-Terrera & others, 2013). Also, in a recent Swedish study, time to death was a good predictor of cognitive decline over time (Bendayan & others, 2017).

## USE IT OR LOSE IT

Changes in cognitive activity patterns might result in disuse and consequent atrophy of cognitive skills (Calero, 2019; Fisher & others, 2017; Kinugawa, 2019; Kunzmann, 2019; Lovden, Backman, & Lindenberger, 2017; Oltmanns & others, 2017; Park & Festini, 2018). This concept is captured by the phrase "use it or lose it." Mental activities that likely benefit the maintenance of cognitive skills in older adults include reading books, doing crossword puzzles, and going to lectures and concerts. "Use it or lose it" also is a significant component of the engagement

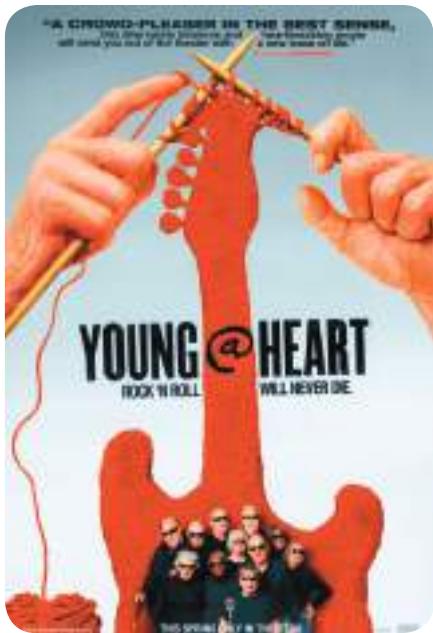

How are education, work, and health linked to cognitive functioning in older adults?

*Greek Playwright, 5th Century B.C.*

model of cognitive optimization that emphasizes how intellectual and social engagement can buffer age-related declines in intellectual development (Mistridis & others, 2017; Reuter-Lorenz & Lustig, 2017). The following studies support the “use it or lose it” concept and the engagement model of cognitive optimization:

- In the Victoria Longitudinal Study, participation in intellectually engaging activities buffered middle-aged and older adults against cognitive decline (Hultsch & others, 1999). Further analyses of the participants in this study revealed that engagement in cognitively complex activities was linked to faster and more consistent processing speed (Bielak & others, 2007). And in the most recent analysis of these older adults over a 12-year period, those who reduced their cognitive lifestyle activities (such as using a computer, playing bridge) subsequently showed decline in cognitive functioning in verbal speed, episodic memory, and semantic memory (Small & others, 2012). The decline in cognitive functioning was linked to subsequent lower engagement in social activities.
- In the Baltimore Experience Corps program, an activities engagement–health promotion for older adults that involved their volunteerism in underserved urban elementary schools—improved older adults’ cognitive and brain functioning (Carlson & others, 2015; Parisi & others, 2012, 2014, 2015).
- In a longitudinal study of 801 Catholic priests 65 years and older, those who regularly read books, did crossword puzzles, or otherwise exercised their minds were 47 percent less likely to develop Alzheimer disease than the priests who rarely engaged in these activities (Wilson & others, 2002).
- Reading daily was linked to increased longevity for men in their seventies (Jacobs & others, 2008).
- At the beginning of a longitudinal study, 75- to 85-year-olds indicated how often they participated in six activities—reading, writing, doing crossword puzzles, playing card or board games, having group discussions, and playing music—on a daily basis (Hall & others, 2009). Across the five years of the study, the point at which memory loss accelerated was assessed and it was found that for each additional activity the older adult engaged in, the onset of rapid memory loss was delayed by 0.18 years. For older adults who participated in 11 activities per week compared with their counterparts who engaged in only 4 activities per week, the point at which accelerated memory decline occurred was delayed by 1.29 years.

## TRAINING COGNITIVE SKILLS

If older adults are losing cognitive skills, can they be retrained? An increasing number of research studies indicate that retraining is possible to some degree (Calero, 2019; Cantarella & others, 2017; Gmial & others, 2018; Kinugawa, 2019; Lopez-Higes & others, 2018; Reuter-Lorenz & Lustig, 2017; Tommaso & others, 2018). Two key conclusions can be derived from research in this area: (1) training can improve the cognitive skills of many older adults, but (2) there is some loss in plasticity in late adulthood, especially in those who are 85 years and older (Baltes, Lindenberger, & Staudinger, 2006). Let’s now examine the results of several cognitive training studies involving older adults.

A study of 60- to 90-year-olds found that sustained engagement in cognitively demanding, novel activities improved the older adults’ episodic memory (Park & others, 2014). To produce this result, the older adults spent an average of 16.5 hours a week for three months learning how to quilt or how to use digital photography. Consider also a recent study of 60- to 90-year-olds in which iPad training 15 hours a week for 3 months improved their episodic memory and processing speed relative to engaging in social or non-challenging activities (Chan & others, 2016).

Researchers are also finding that improving the physical fitness of older adults can improve their cognitive functioning (Coetsee & Terblanche, 2018; Erickson & Liu-Ambrose, 2016; Gmial & others, 2018; Erickson & Oberlin, 2017; Strandberg, 2019; Walker, 2019). A research review revealed that aerobic fitness training in older adults improved their performance in the areas of planning, scheduling, working memory, resistance to distraction, and handling multiple tasks (Colcombe & Kramer, 2003). In another research review, engaging in low or moderate exercise was linked to improved cognitive functioning in older adults with chronic diseases

*To what extent can training improve cognitive functioning of older adults?*

©Blend Images/Alamy

(Cai & others, 2017). Also, in a recent study, engagement in physical activity in late adulthood was linked to less cognitive decline (Gow, Pattie, & Deary, 2017).

Meta-examinations of four longitudinal observational studies (Long Beach Longitudinal Study; Origins of Variance in the Oldest-old [Octo-Twin] Study in Sweden; Seattle Longitudinal Study; and Victoria Longitudinal Study in Canada) of older adults' naturalistic cognitive activities found that changes in cognitive activity predicted cognitive outcomes as long as two decades later (Brown & others, 2012; Lindwall & others, 2012; Mitchell & others, 2012). However, the studies provided no support for the concept that engaging in cognitive activity at an earlier point in development improved older adults' ability to later withstand cognitive decline. On a positive note, when older adults continued to increase their engagement in cognitive and physical activities, they were better able to maintain their cognitive functioning in late adulthood.

The Stanford Center for Longevity (2011) and the Stanford Center for Longevity in partnership with the Max Planck Institute for Human Development (2014) reported information based on the views of leading scientists in the field of aging. One of their concerns is the misinformation given to the public touting products to improve the functioning of the mind for which there is no scientific evidence. Nutritional supplements, brain games, and software products have all been advertised as "magic bullets" to slow the decline of mental functioning and improve the mental ability of older adults. Some of the claims are reasonable but not scientifically tested, while others are unrealistic and implausible (Willis & Belleville, 2016). A research review of dietary supplements and cognitive aging did indicate that ginkgo biloba was linked with improvements in some aspects of attention in older adults and that consuming omega-3 polyunsaturated fatty acids (fish oil) was related to reduced risk of age-related cognitive decline (Gorby, Brownawell, & Falk, 2010). In this research review, there was no evidence of cognitive improvements in aging adults who took supplements containing ginseng and glucose. Also, an experimental study with 50- to 75-year-old females found that those who took fish oil for 26 weeks had improved executive function and beneficial effects on a number of areas of brain functioning compared with their female counterparts who took a placebo pill (Witte & others, 2014). In another study, fish oil supplement use was linked to higher cognitive scores and less atrophy in one or more brain regions (Daiello & others, 2015). And in a recent study, fish oil supplementation improved the working memory of older adults (Boespflug & others, 2016). Overall, though, most research has not provided consistent plausible evidence that dietary supplements can accomplish major cognitive goals in aging adults over a number of years.

However, some software-based cognitive training games have been found to improve older adults' cognitive functioning (Charness & Boot, 2016; Lampit & others, 2015; Nouchi & others, 2013; Ordonez & others, 2017; Szelag, 2018). For example, a study of 60- to 85-year-olds found that a multitasking video game that simulates day-to-day driving experiences (NeuroRacer) improved cognitive control skills, such as sustained attention and working memory, after training on the video game and six months later (Anguera & others, 2013). In another recent study, computerized cognitive training slowed the decline in older adults' overall memory performance, an outcome that was linked to enhanced connectivity between the hippocampus and prefrontal cortex (Suo & others, 2016). In a research meta-analysis, computerized cognitive training resulted in modest improvement in some cognitive processes (nonverbal memory, verbal memory, working memory, processing speed, and visuospatial skills) but did not improve executive function and attention (Lampit, Hallock, & Valenzuela, 2014). And in another recent study, cognitive training using virtual reality-based games with stroke patients improved their attention and memory (Gamito & others, 2017). Nonetheless, it is possible that the training games may improve cognitive skills in a laboratory setting but not generalize to gains in the real world.

After examining research findings, Stanford Center for Longevity and the Max Planck Institute for Human Development (2014) concluded that the effectiveness of brain games has often been exaggerated and the research evidence for many success claims is often weak or unfounded. They also concluded that there is little evidence that playing brain games in late adulthood improves underlying broad cognitive abilities or that the games help older adults to function more competently in everyday life.

In sum, some improvements in the cognitive vitality of older adults can be accomplished through some types of cognitive, physical activity, and nutritional interventions (Bo & others, 2017; Erickson & Oberlin, 2017; Faroli-Vecchioli & others, 2018; Gillian & others, 2019; Perkis & Vandewoude, 2019; Reuter-Lorenz & Lustig, 2017; Strandberg, 2019). However,

benefits have not been observed in all studies (Salthouse, 2007, 2017). Further research is needed to determine more precisely which cognitive improvements occur in older adults as a result of training (Salthouse, 2017).

## COGNITIVE NEUROSCIENCE AND AGING

### developmental connection

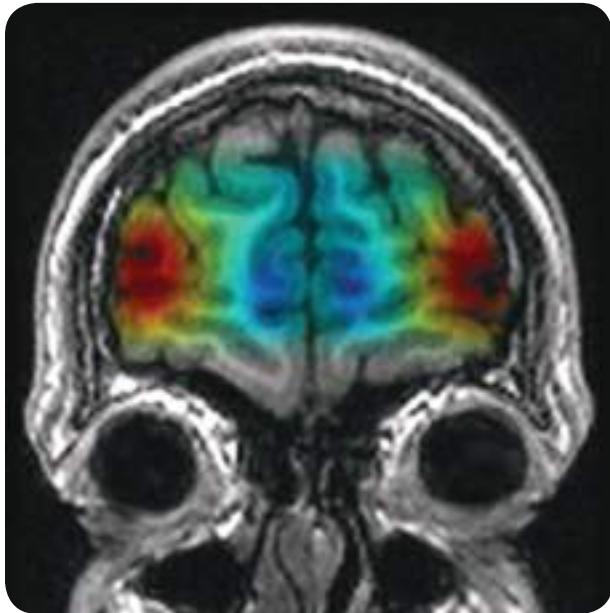

#### Brain Development

The activities older adults engage in can influence the brain's development. Connect to "Physical Development in Late Adulthood."

We have seen that certain regions of the brain are involved in links between aging and cognitive functioning. In this section, we further explore the substantial increase in interest in the brain's role in aging and cognitive functioning. The field of *cognitive neuroscience* has emerged as the major discipline that explores the links between brain activity and cognitive functioning (Kennedy & others, 2017; Kinugawa, 2019; Nyberg, Pudas, & Lundquist, 2017; Park & Festini, 2018; Riekmann, Buckner, & Hedden, 2017). This field especially relies on brain-imaging techniques such as fMRI, PET, and DTI (diffusion tensor imaging) to reveal the areas of the brain that are activated when individuals engage in certain cognitive activities (Madden & Parks, 2017; Park & Festini, 2017, 2018). For example, as an older adult is asked to encode and then retrieve verbal materials or images of scenes, the older adult's brain activity will be monitored by an fMRI brain scan.

Changes in the brain can influence cognitive functioning, and changes in cognitive functioning can influence the brain (Kinugawa, 2019). For example, aging of the brain's prefrontal cortex may produce a decline in working memory (Reuter-Lorenz & Lustig, 2017). And when older adults do not regularly use their working memory (recall the section on "Use It or Lose It"), neural connections in the prefrontal lobe may atrophy. Further, cognitive interventions that activate older adults' working memory may increase these neural connections.

Despite being in its infancy as a field, the cognitive neuroscience of aging is beginning to uncover some important links between aging, the brain, and cognitive functioning (Berron & others, 2018; Bettio, Rajendran, & Gil-Mohapel, 2017; Cabeza, Nyberg, & Park, 2017; Ezaki & others, 2018; Kinugawa, 2019; Park & Festini, 2018; Reuter-Lorenz & Lustig, 2017; Rugg, 2017). These include the following:

**FIGURE 3**

**THE PREFRONTAL CORTEX.** Advances in neuroimaging are allowing researchers to make significant progress in connecting changes in the brain with cognitive development. Shown here is an fMRI of the brain's prefrontal cortex. *What links have been found between the prefrontal cortex, aging, and cognitive development?*

Courtesy of Dr. Sam Gilbert, Institute of Cognitive Neuroscience, UK

- Neural circuits in specific regions of the brain's prefrontal cortex decline, and this decline is linked to poorer performance by older adults on tasks involving complex reasoning, cognitive inhibition, working memory, and episodic memory (Grady & others, 2006; Reuter-Lorenz & Lustig, 2017) (see Figure 3).
- Older adults are more likely than younger adults to use both hemispheres of the brain to compensate for declines in attention, memory, executive function, and language that occur with age (Davis & others, 2012; Dennis & Cabeza, 2008; Reuter-Lorenz, Festini, & Jantz, 2016). For example, two neuroimaging studies found that older adults showed better memory performance when both hemispheres of the brain were active in processing information (Angel & others, 2011; Manenti, Cotelli, & Miniussi, 2011).
- Functioning of the hippocampus declines to a lesser degree than the functioning of the frontal lobes in older adults (Antonenko & Floel, 2014). In K. Warner Schaie's (2013) research, individuals whose memory and executive function declined in middle age had more hippocampal atrophy in late adulthood, but those whose memory and executive function improved in middle age did not show a decline in hippocampal functioning in late adulthood.
- Patterns of neural decline with aging are more dramatic for retrieval than for encoding (Gutchess & others, 2005).
- Compared with younger adults, older adults often show greater activity in the frontal and parietal lobes of the brain on simple tasks but as attentional demands increase, older adults display less effective functioning in areas of the frontal and parietal lobes of the brain that are involved in cognitive control (Campbell & others, 2012).

- Cortical thickness in the frontoparietal network predicts executive function in older adults (Schmidt & others, 2016).
- Younger adults have better connectivity between brain regions than older adults do (Archer & others, 2016; Damoiseaux, 2017; Madden & Parks, 2017). For example, one study revealed that younger adults had more connections between brain activations in frontal, occipital, and hippocampal regions than older adults during a difficult encoding task (Leshikar & others, 2010).
- An increasing number of cognitive and physical fitness training studies are using brain-imaging techniques such as fMRI to assess the results of such training on brain function (Cooper, Moon, & van Praag, 2018; Erickson & Liu-Ambrose, 2016; Erickson & Oberlin, 2017; Flodin & others, 2017; Kinugawa, 2019; Macpherson & others, 2017; Walker, 2019). In one study, older adults who walked one hour a day three days a week for six months showed increased volume in the frontal and temporal lobes of the brain (Colcombe & others, 2006).

Denise Park and Patricia Reuter-Lorenz (2009) proposed a neurocognitive scaffolding view of connections between the aging brain and cognition. In this view, increased activation in the prefrontal cortex with aging reflects an adaptive brain that is compensating for declining neural structures and function and declines in various aspects of cognition, including working memory and long-term memory. Scaffolding involves the use of complementary neural circuits to protect cognitive functioning in an aging brain. Among the factors that can strengthen brain scaffolding are cognitive engagement and exercise.

## Review Connect Reflect

**LG1** Describe the cognitive functioning of older adults.

### Review

- How is cognition multidimensional and multidirectional in older adults?
- What changes in cognitive processing take place in aging adults?
- How do education, work, and health affect cognition in aging adults?
- What is the concept of “use it or lose it”?
- To what extent can older adults’ cognitive skills be retrained?
- What characterizes the cognitive neuroscience of aging?

### Connect

- The term *scaffolding* was used in this section to describe the use of complementary neural circuits to

protect cognitive functioning in an aging brain. How has the term *scaffolding* been used elsewhere in the text?

### Reflect Your Own Personal Journey of Life

- Can you think of older adults who have made significant contributions in late adulthood, other than those we mentioned in the chapter? Spend some time reading about these individuals and evaluate how their intellectual interests contributed to their life satisfaction as older adults. What did you learn from their lives that might benefit your cognitive development and life satisfaction as an older adult?

## 2 Language Development

**LG2** Characterize changes in language skills in older adults.

Most research on language development has focused on infancy and childhood. It is generally thought that for most of adulthood individuals maintain their language skills (Wingfield & Lash, 2016). The vocabulary of individuals often continues to increase throughout most of the adult years, at least until late adulthood (Schaie, 2013; Singh-Manoux & others, 2012). Many older adults maintain or improve their word knowledge and word meaning (Burke & Shafto, 2004).

In late adulthood, however, some decrements in language skills may appear (Antonenko & others, 2013; Obler, 2009; Payne & Federmeier, 2018; Valech & others, 2018). Among the most common language-related complaints reported by older adults are difficulty in

retrieving words to use in conversation and problems understanding spoken language in certain contexts (Clark-Cotton & others, 2007). This often involves the *tip-of-the-tongue phenomenon* mentioned earlier, in which individuals are confident that they know something but can't quite seem to retrieve it from memory (James & others, 2018). Older adults also report that in less than ideal listening conditions they can have difficulty understanding speech. This difficulty is most likely to occur when speech is rapid, competing stimuli are present (a noisy room, for example), and when they can't see their conversation partner (in a telephone conversation, for example). The difficulty in understanding speech may be due to hearing loss as well as cognitive impairment (Benichov & others, 2012). In general, though, most language skills decline little among older adults if they are healthy (Wingfield & Lash, 2016).

Some aspects of the phonological skills of older adults are different from those of younger adults (Matty & Scharenborg, 2014; Robert & Mathey, 2018). Older adults' speech is typically lower in volume, slower, less precisely articulated, and less fluent (more pauses, fillers, repetition, and corrections). Despite these age differences, most older adults' speech skills are adequate for everyday communication.

Researchers have found conflicting information about changes in *discourse* (extended verbal expression in speech or writing) with aging. "Some (researchers) have reported increased elaborateness, while others have reported less varied and less complex syntax" (Obler, 2009, p. 459). One aspect of discourse where age differences have been found involves retelling a story or giving instructions for completing a task. When engaging in this type of discourse, older adults are more likely than younger adults to omit key elements, creating discourse that is less fluent and more difficult to follow (Clark-Cotton & others, 2007). One study found that when retelling a story, older adults were more likely than younger adults to compress discourse and less likely to improve the cohesiveness of their narratives (Saling, Laroo, & Saling, 2012).

Nonlanguage factors may be responsible for some of the declines in language skills that do occur in older adults (Obler, 2009). Slower information-processing speed and a decline in working memory, especially in being able to keep information in mind while processing, likely contribute to decreased language efficiency in older adults (Salthouse, 2017). For example, a recent study found that the lower working memory capacity of older adults compared with younger adults impaired their comprehension of sentences (Sung & others, 2017).

Language skills decline among individuals with Alzheimer disease, as we will discuss later in the chapter (Valech & others, 2018). Word-finding/generating difficulties are one of the earliest symptoms of Alzheimer disease (Haugrud, Crossley, & Vrbancic, 2011). Individuals with Alzheimer disease especially have difficulty on tests of semantic verbal fluency, in which they have to say as many words as possible in a category (fruits or animals, for example) in a given time, typically one minute (Pakhomov, Hemmy, & Lim, 2012; Weakley & Schmitter-Edgecombe, 2014). Most individuals with the disease do retain much of their ability to produce well-formed sentences until the late stages of the disease. Nonetheless, they do make more grammatical errors than older adults without the disease (Huang, Meyer, & Federmeier, 2012; Kail, Lemaire, & Lecacheur, 2012). In a recent study, individuals with Alzheimer disease were less likely to use syntactic components in their language than those who did not have Alzheimer disease (Orimaye & others, 2017).

Recently, interest has been generated by the possibility that bilingualism may delay the onset of Alzheimer disease (Antoniou & Wright, 2017; Bialystok, 2017; Bialystok & others, 2016; Borsa & others, 2018). One study found that the onset of Alzheimer disease occurred 4.5 years later in bilingual older adults than in their counterparts who were not bilingual (Alladi & others, 2013). Another study revealed that the onset of symptoms and first office visit for Alzheimer disease occurred several years later for bilingual than for monolingual older adults (Bialystok & others, 2014). These results led Ellen Bialystok and her colleagues (2016) to recently conclude that being bilingual may be one of the best ways to delay the onset of Alzheimer disease by as much as four to five years. It is not yet clear why the advantage occurs for bilingual older adults, but one explanation might be better executive function (Gasquoine, 2016). For example, a recent study found that bilingual Alzheimer patients had better neural network functioning, especially in the neural network involving executive function, than did monolingual Alzheimer patients (Perani & others, 2017).

## Review Connect Reflect

**LG2** Characterize changes in language skills in older adults.

### Review

- What are the main changes in language skills in older adults?

### Connect

- In this section, we learned that some aspects of the phonological skills of older adults are different from those of younger adults. By what age are

children typically capable of producing all the vowel sounds and most of the consonant sounds of their language?

### Reflect Your Own Personal Journey of Life

- What might you be able to do as an older adult to preserve or even enhance your language skills?

## 3 Work and Retirement

**LG3** Discuss aging and adaptation to work and retirement.

Work

Retirement in the United States and in Other Countries

Adjustment to Retirement

What percentage of older adults continue to work? How productive are they? Who adjusts best to retirement? What is the changing pattern of retirement in the United States and around the world? Let's look at the answers to these and other questions.

### WORK

In 2000, 23 percent of U.S. 65- to 69-year-olds were in the workforce; in 2017, this percentage had jumped to 32 percent (Mislinksi, 2018). Among 70- to 74-year-olds, 13 percent were in the workforce in 2000, but this percentage had increased to 19 percent in 2015. The increased percentage of older adults who continue to work has occurred more for women than men. For example, the labor force participation for 75-and-over women has risen 87 percent since 2000, while participation in the work force for 75-and-over men has increased 45 percent (Mislinksi, 2018). These increases likely are mainly driven by the need to have adequate money to meet living expenses in old age (Cahill, Giandrea, & Quinn, 2016). The U.S. Labor Department projects that by 2020 35 percent of 65- to 74-year-old men and 28 percent of 65- to 74-year-old women will be in the workforce (Hayutin, Beals, & Borges, 2013). A recent study found the following were among the most important motives and preconditions older workers worked beyond retirement age: financial, health, knowledge, and purpose in life (Sewdas & others, 2017).

Research suggests that U.S. workers are reasonably satisfied with their jobs and that older U.S. workers are the most satisfied of all age groups (AP-NORC Center for Public Affairs Research, 2013). However, there are significant individual variations in worker satisfaction at all adult ages (Antonucci & others, 2016).

Cognitive ability is one of the best predictors of job performance in older adults (Fisher & others, 2017; Lovden, Backman, & Lindenberger, 2017). And older workers have lower rates of absenteeism, fewer accidents, and higher job satisfaction than their younger counterparts (Warr, 2004). Thus, the older worker can be of considerable value to a company, above and beyond the older worker's cognitive competence. Changes in federal law now allow individuals over the age of 65 to continue working (Shore & Goldberg, 2005). Also, remember from our discussion earlier in this chapter that substantively complex work is linked with a higher level of intellectual functioning (Schooler, 2007; Wang & Shi, 2016). Further, researchers have found that working in an occupation with a high level of mental demands is linked to higher levels of cognitive functioning before retirement and a slower rate of cognitive decline after retirement (Fisher & others, 2014). In sum, a cognitively stimulating work context promotes successful aging (Fisher & others, 2017; Lovden, Backman, & Lindenberger, 2017).

Several recent studies also have found that older adults who work have better physical and cognitive profiles than those who retire. For example, one study found that physical functioning declined faster in retirement than in full-time work for individuals 65 years of age and older, with the difference not explained by absence of chronic diseases and lifestyle risks

### developmental connection

#### Work

In the United States, approximately 80 percent of individuals 40 to 59 years of age are employed. Connect to "Physical and Cognitive Development in Middle Adulthood."

The night hath not yet come:  
We are not quite cut off from  
labor by the failing of light;  
some work remains for us to  
do and dare.

—HENRY WADSWORTH LONGFELLOW  
*American Poet, 19th Century*

Ninety-two-year-old Russell "Bob" Harrell (right) puts in 12-hour days at Sieco Consulting Engineers in Columbus, Indiana. A highway and bridge engineer, he designs and plans roads. James Rice (age 48), a vice president of client services at Sieco, says that Bob wants to learn something new every day and that he has learned many life lessons from being around him. Harrell says he is not planning to retire. *What are some variations in work and retirement in older adults?*

©Greg Sailor

(Stenholm & others, 2014). Another study revealed that retirement increased the risk of having a heart attack in older adults (Olesen & others, 2014). Further, a recent study found that individuals who retired for health reasons had lower verbal memory and verbal fluency than their counterparts who retired voluntarily or for family reasons (Denier & others, 2017). And in another recent study of older adults, those who continued to work in paid jobs had better physical and cognitive functioning than retirees (Tan & others, 2017).

In sum, age affects many aspects of work (Cahill, Giandrea, & Quinn, 2016; Lovden, Backman, & Lindenberger, 2017; Wang & Shi, 2016). Nonetheless, many studies of work and aging—such as evaluation of hiring and performance—have yielded inconsistent results. Important contextual factors—such as age composition of departments or applicant pools, occupations, and jobs—all affect decisions about older workers. It also is important to recognize that ageist stereotypes of workers and of tasks can limit older workers' career opportunities and can encourage early retirement or other forms of downsizing that adversely affect older workers (Finkelstein & Farrell, 2007). A study of older workers found that accurately self-evaluating one's skills and values, being positive about change, and participating in a supportive work environment were linked to adaptive competence on the job (Unson & Richardson, 2013).

## RETIREMENT IN THE UNITED STATES AND IN OTHER COUNTRIES

At what age do most people retire in the United States? Do many people return to the workforce at some point after they have retired? What is retirement like in other countries?

**Retirement in the United States** The option to retire is a late-twentieth-century phenomenon in the United States (Coe & others, 2012). It exists largely because of the 1935 implementation of the Social Security system, which gives benefits to older workers when they retire. On average, today's workers will spend 10 to 15 percent of their lives in retirement. A survey revealed that as baby boomers move into their sixties, they expect to retire later than their parents or their grandparents did (Frey, 2007). In 2017, in the United States, the average age of retirement for men was 64 and for women 62 (Anspach, 2017). The labor force participation for women is now very close to that of men, especially among workers over 65 years of age (Munnell, 2015). The average number of years spent in retirement by Americans is 18 years. A recent study found that baby boomers expect to work longer than their predecessors in prior generations (Dong & others, 2017).

In the past, when most people reached an accepted retirement age, such as some point in their sixties, retirement meant a one-way exit from full-time work to full-time leisure. Increasingly, individuals are delaying retirement and moving into and out of work as the traditional lock-step process of full-time work to full-time retirement occurs less often (Cahill & others, 2018; Kojola & Moen, 2016). Currently, there is no single dominant pattern of retirement but rather a diverse mix of pathways involving occupational identities, finances, health, and expectations and perceptions of retirement (Kojola & Moen, 2016). Leading expert Phyllis Moen (2007) described how increasingly when people reach their sixties, the life path they follow is less clear:

- Some individuals don't retire, continuing in their career jobs.
- Some retire from their career work and then take up a new and different job.
- Some retire from career jobs but do volunteer work.
- Some retire from a post-retirement job and go on to yet another job.
- Some move in and out of the workforce, so they never really have a "career" job from which they retire.
- Some individuals who are in poor health move to a disability status and eventually into retirement.
- Some who are laid off define it as "retirement."

Approximately 7 million retired Americans return to work after they have retired (Putnam Investments, 2006). When retired adults return to the labor force, it occurs on average four years after retirement (Hardy, 2006). In many instances, the jobs pay much less than their pre-retirement jobs. In one study of older adults who returned to work, approximately

two-thirds said they were happy they had done so, while about one-third indicated they were forced to go back to work to meet financial needs (Putnam Investments, 2006).

Just as the life path after individuals reach retirement age may vary, so do their reasons for working. For example, some older adults who reach retirement age work for financial reasons, others to stay busy, and yet others to “give back” (Moen, 2007).

**Work and Retirement in Other Countries** What characterizes work and retirement in other countries? One analysis concluded that France has the earliest average retirement age of 60 for men and 61 for women (OECD, 2017). In this analysis, Korea had the oldest average retirement age of 72 for men and 73 for women.

A large-scale study of 21,000 individuals aged 40 to 79 in 21 countries examined patterns of work and retirement (HSBC Insurance, 2007). On average, 33 percent of individuals in their sixties and 11 percent in their seventies were still in some kind of paid employment. In this study, 19 percent of those in their seventies in the United States were still working. A substantial percentage of individuals expect to continue working as long as possible before retiring (HSBC Insurance, 2007).

In the study of work and retirement in 21 countries, Japanese retirees missed the work slightly more than they expected and the money considerably less than they expected (HSBC Insurance, 2007). U.S. retirees missed both the work and the money slightly less than they expected. German retirees were the least likely to miss the work, Turkish and Chinese retirees the most likely to miss it. Regarding money, Japanese and Chinese retirees were the least likely to miss it, Turkish retirees the most likely to miss it.

Early retirement policies were introduced by many companies in the 1970s and 1980s with the intention of making room for younger workers (Coe & others, 2012). A recent research review found that workplace organizational pressures, financial security, and poor physical and mental health were antecedents of early retirement (Topa, Depolo, & Alcover, 2018). However, increasing number of adults are beginning to reject the early retirement option as they hear about people who retired and then regretted it. In a 21-country study, on average only 12 percent of individuals in their forties and fifties expected to take early retirement while 16 percent in their sixties and seventies had taken early retirement (Coe & others, 2012). Only in Germany, South Korea, and Hong Kong did a higher percentage of individuals expect to take early retirement than in the past.

## ADJUSTMENT TO RETIREMENT

Retirement is a process, not an event (Wang & Shi, 2016). Much of the research on retirement has been cross-sectional rather than longitudinal and has focused on men rather than women. One study found that men had higher morale when they had retired within the last two years compared with men who had been retired for longer periods of time (Kim & Moen, 2002). Another study revealed that retired married and remarried women reported being more satisfied with their lives and in better health than retired women who were widowed, separated, divorced, or had never been married (Price & Joo, 2005). Yet another study indicated that women spend less time planning for retirement than men do (Jacobs-Lawson, Hershey, & Neukam, 2005). Another study revealed that higher levels of financial assets and job satisfaction were more strongly linked to men’s higher psychological well-being in retirement, while preretirement social contacts were more strongly related to women’s psychological well-being in retirement (Kubicek & others, 2010).

Older adults who adjust best to retirement are healthy, have adequate income, are active, are better educated, have an extended social network including both friends and family, and usually were satisfied with their lives before they retired (Damman, Henkens, & Kalmijn, 2015; Ilmakunnas & Ilmakunnas, 2018; Miller, 2018). Older adults with inadequate income and poor health, and those who must adjust to other stress that occurs at the same time as retirement, such as the death of a spouse, have the most difficult time adjusting to retirement (Reichstadt & others, 2007).

As mentioned earlier, the U.S. retirement system is in transition (Biro & Elek, 2018; Mossburg, 2018). A 2017 survey indicated that only 18 percent of American workers feel very confident that they will have enough money to have a comfortable retirement (Greenwald, Copeland, & VanDerhei, 2017). However, 60 percent said they feel somewhat or very confident they will have enough money to live comfortably in retirement. In this survey, 30 percent of American workers reported that preparing for retirement made them feel mentally or

*In the study of work and retirement in 21 countries, what were some variations across countries regarding the extent to which retirees missed work and money?*

emotionally distressed. In regard to retirement income, the two main worries of individuals as they approach retirement are: (1) having to draw retirement income from savings, and (2) paying for health-care expenses (Yakoboski, 2011).

Flexibility is also a key factor in whether individuals adjust well to retirement (Mossburg, 2018; Wang & Shi, 2016). When people retire, they no longer have the structured environment they had when they were working, so they need to be flexible and discover and pursue their own interests. Cultivating interests and friends unrelated to work improves adaptation to retirement.

Planning ahead and then successfully carrying out the plan are important aspects of adjusting well in retirement (Topa, Lunceford, & Boyatzis, 2018; Treiger, 2016). A special concern in retirement planning involves women, who are likely to live longer than men, more likely to live alone, and tend to have lower retirement income (less likely to remarry and more likely to be widowed) (Prickett & Angel, 2011).

It is important not only to plan financially for retirement but also to consider other aspects of your life (Topa, Lunceford, & Boyatzis, 2018; Wang & Shi, 2016). In addition to financial planning, individuals need to ask questions about retirement such as these: What am I going to do with my leisure time? How am I going to stay physically fit? What am I going to do socially? What am I going to do to keep my mind active?

## Review Connect Reflect

**LG3** Discuss aging and adaptation to work and retirement.

### Review

- What characterizes the work of older adults?
- Compare retirement in the United States with retirement in other countries.
- How can individuals adjust effectively to retirement?

### Connect

- U.S. adolescents spend much more time in unstructured leisure activities

than East Asian adolescents do. How might establishing challenging lifelong leisure activities as an adolescent benefit an individual at retirement age?

### Reflect Your Own Personal Journey of Life

- At what age would you like to retire? Or would you prefer to continue working as an older adult as long as you are healthy?

## 4 Mental Health

**LG4** Describe mental health problems in older adults.

Depression

Dementia, Alzheimer Disease, and Other Afflictions

Although a substantial portion of the population can now look forward to a longer life, that life may unfortunately be hampered by a mental disorder in old age (Brown & Wolf, 2017; Bruce & Sirey, 2018; Guo & others, 2018; Szanto & others, 2018; van den Brink & others, 2018). This prospect is both troubling to the individual and costly to society. Mental disorders make individuals increasingly dependent on the help and care of others. The cost of caring for older adults with mental health disorders is estimated to be more than \$40 billion per year in the United States. More important than the loss in dollars, though, is the loss of human potential and the suffering involved for individuals and their families (Frank & others, 2018; Wolff & others, 2017). Although mental disorders in older adults are a major concern, it is important to understand that older adults do not have a higher incidence of mental disorders than younger adults do (Busse & Blazer, 1996).

### DEPRESSION

**Major depression** is a mood disorder in which the individual is deeply unhappy, demoralized, self-derogatory, and bored. The person does not feel well, loses stamina easily, has poor appetite, and is listless and unmotivated. Major depression is so widespread that it has been called the “common cold” of mental disorders.

**major depression** A mood disorder in which the individual is deeply unhappy, demoralized, self-derogatory, and bored. The person does not feel well, loses stamina easily, has poor appetite, and is listless and unmotivated. Major depression is so widespread that it has been called the “common cold” of mental disorders.

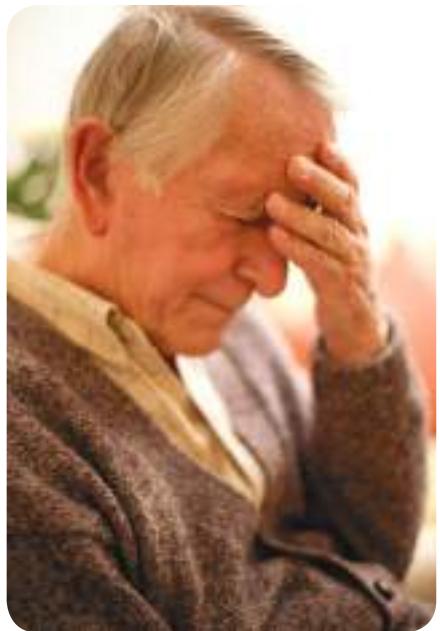

of mental disorders. A recent research review concluded that in the last two decades when compared to younger adults, depression in older adults is not more common and is not more often caused by psychological factors (Haigh & others, 2018). Also, it was found that compared with middle-aged adults, depression in older adults is more likely to be chronic (that is, has a higher rate of relapse), which is likely linked to higher rates of medical problems in older adults (Haigh & others, 2018).

One study found that the lower frequency of depressive symptoms in older adults compared with middle-aged adults was linked to fewer economic hardships, fewer negative social interchanges, and increased religiosity (Schieman, van Gundy, & Taylor, 2004). Other research indicates that older adults who engage in regular exercise, especially aerobic exercise, are less likely to be depressed, whereas those who are in poor health and experiencing pain are more likely to be depressed (Cimpean & Drake, 2011). Depressive symptoms increase among the oldest-old (85 years and older), and this increase is associated with a higher percentage of women in the group, more physical disability, greater cognitive impairment, and lower socio-economic status (Hybels & Blazer, 2004).

In childhood, adolescence, and early adulthood, females have higher rates of depression than males do (Nolen-Hoeksema, 2011). Does this gender difference hold for middle-aged and older adults? For most of late adulthood, women are more likely to have a higher rate of depression and have more severe depression than are males, with these differences narrowing only among the oldest-old (Barry & Byers, 2016). These gender differences in depression among older adults likely reflect factors such as women having lower incomes and having one or more chronic illnesses.

Among the most common predictors of depression in older adults are earlier depressive symptoms, poor health, disability, losses such as the death of a spouse, low social support, and social isolation (Park & others, 2018; Saint Onge, Krueger, & Rogers, 2014; Taylor & others, 2018; Wermelinger Avila & others, 2018). In a recent study, suicidal ideation was strongly associated with depression severity in older adults (Rossom & others, 2018). In this study, older adults who had moderate to severe depression were 48 times more likely to engage in suicidal ideation than their counterparts who had minimal to mild depressive symptoms. Insomnia is often overlooked as a risk factor for depression in older adults (Fiske, Wetherell, & Gatz, 2009). Curtailment of daily activities also is a common pathway to late-life depression (Fiske, Wetherell, & Gatz, 2009). Often accompanying this curtailment of activity is an increase in self-critical thinking that exacerbates depression. A meta-analysis found that the following living arrangements were linked to increased risk for depression in older adults: living alone, in a nursing home, or in an institutionalized setting (Xiu-Ying & others, 2012). Also, in a recent study of community-dwelling older adults, engaging in light physical exercise, taking lessons, using a computer, and participating in community events predicted a lower level of depressive symptoms (Uemura & others, 2018).

Depression is a treatable condition, not only in young adults but in older adults as well (Bruce & Sirey, 2018; Casey, 2017; Frank & others, 2018; Raue & others, 2017). Unfortunately, up to 80 percent of older adults with depressive symptoms receive no treatment at all. Combinations of medications and psychotherapy produce significant improvement in almost four out of five older adults with depression (Koenig & Blazer, 1996). In a recent research review it was concluded that depressed older adults respond to psychological treatments as well as younger adults do (Haigh & others, 2017). However, this review found that antidepressants are less effective with older adults than younger adults. Researchers have discovered that electroconvulsive treatment (ECT) is more effective in treating older adults' depression than antidepressants (Dols & others, 2017; Rhebergen & others, 2015; Spaans & others, 2015). Further, exercise can reduce depression in older adults (Chang & others, 2017, 2018; Holmquist & others, 2017). For example, a study of older adults found that even light-intensity exercise was linked to a lower level of depression (Loprinzi, 2013). Another recent study revealed that older adults who had the highest levels of physical activity and who engaged in athletic activities were at a lower risk for depression (Joshi & others, 2016). And in a Taiwanese study, consistent exercise of 15 minutes or more at a time of moderate intensity three times a week was associated with a lower risk of developing depressive symptoms (Chang & others, 2017). Also, engagement in valued activities and religious/spiritual involvement can reduce depressive symptoms (Krause & Hayward, 2016). Life review/reminiscence therapy, which we will discuss further in the chapter on "Socioemotional Development in Late Adulthood," is linked to a reduction in depressive symptoms and underutilized in the treatment of depression in older

What characterizes depression in older adults?

### developmental connection

#### Gender

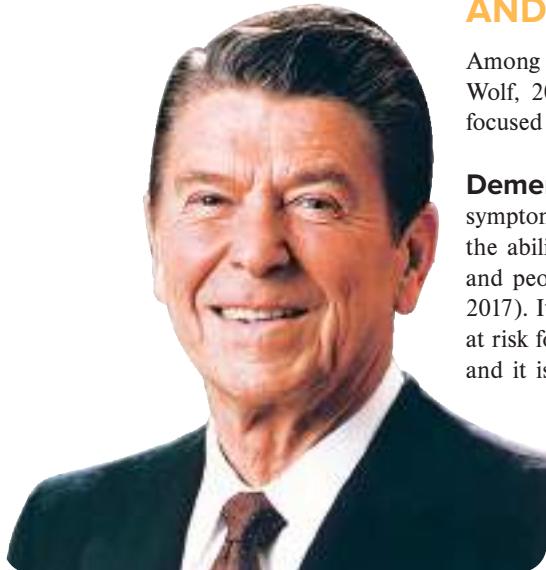

One reason females have higher rates of depression is that they ruminate more in their depressed mood and amplify it more than males do. Connect to "Socioemotional Development in Adolescence."

adults (Rita Chang & Chien, 2018; Siverova & Buzgova, 2018; Wu & others, 2018; Yen & Lin, 2018). Further, researchers have found that depressed older adults are less likely to receive treatment for their depression than younger adults are (Sanglier & others, 2015).

Major depression can result not only in sadness but also in suicidal tendencies (Barry & Byers, 2016; Choi & others, 2017; Okolie & others, 2017; Park & others, 2018; Szanto & others, 2018). Recent national statistics indicate that the highest suicide rate occurs for 45- to 64-year-olds (19.6 per 100,000 individuals), followed by individuals 85 years or older (19.4 per 100,000 individuals) (Centers for Disease Control and Prevention, 2015). For older adults aged 65 to 84, the rate per 100,000 individuals was 16.1, similar to the rate for individuals 20 to 34 (15.5).

The older adult most likely to commit suicide is a male who lives alone, has lost his spouse, and is experiencing failing health (Balasubramaniam, 2018; Ruckenhauser, Yazdani, & Ravaglia, 2007). A recent study further explored the influencing and protective factors involving suicidal ideation in older adults (Huang & others, 2017). In this study, the triggers for suicidal ideation included physical discomfort, loss of respect and/or support from family, impulsive emotions due to conflicts with others, and painful memories. Psychological factors contributing to suicidal ideation included feelings of loneliness, sense of helplessness, and low self-worth. Protective factors that were linked to lower levels of suicidal ideation included support from family and friends, emotional control, a support network, and comfort from religion. Further, a recent study found that declines in socioeconomic status were linked to increased suicide attempts in older adults (Dombrovski & others, 2018).

## DEMENTIA, ALZHEIMER DISEASE, AND OTHER AFFLICTIONS

Former U.S. president Ronald Reagan was diagnosed with Alzheimer disease at age 83.

©Bettmann/Getty Images

**dementia** A global term for any neurological disorder in which the primary symptoms involve a deterioration of mental functioning.

**Alzheimer disease** A progressive, irreversible brain disorder characterized by a gradual deterioration of memory, reasoning, language, and eventually, physical function.

Among the most debilitating of mental disorders in older adults are the dementias (Brown & Wolf, 2018; Castro-Monteiro & others, 2016). In recent years, extensive attention has been focused on the most common dementia, Alzheimer disease.

**Dementia** **Dementia** is a global term for any neurological disorder in which the primary symptoms involve a deterioration of mental functioning. Individuals with dementia often lose the ability to care for themselves and can become unable to recognize familiar surroundings and people—including family members (Dooley, Bass, & McCabe, 2018; Morikawa & others, 2017). It is estimated that 23 percent of women and 17 percent of men 85 years and older are at risk for developing dementia (Alzheimer's Association, 2013). Dementia is a broad category, and it is important that every effort is made to determine the specific cause of deteriorating mental functioning (Hagenaars & others, 2017; Garcia Basalo & others, 2017; MacNeil Vroomen & others, 2018; Mao & others, 2018). In one recent study, a 2-year multi-domain intervention of diet, exercise, cognitive training, and vascular risk monitoring improved or maintained the cognitive functioning of 60- to 77-year-olds at risk for developing dementia (Ngandu & others, 2015). And in another recent study, a 12-week online program (consisting of modules on activity, goal-monitoring, diet, social engagement, cognitive engagement, and management of chronic conditions) reduced the dementia risks of middle-aged adults with multiple risk factors (Anstey & others, 2015).

**Alzheimer Disease** One form of dementia is **Alzheimer disease**—a progressive, irreversible brain disorder that is characterized by a gradual deterioration of memory, reasoning, language, and eventually, physical function. In 2017, an estimated 5.5 million adults in the United States had Alzheimer disease, and it is projected that 10 million baby boomers will develop Alzheimer disease in their lifetime (Alzheimer's Association, 2017). Ten percent of individuals 65 and older have Alzheimer disease. The percentage of individuals with Alzheimer disease increases dramatically with age: 3 percent aged 65 to 74, 17 percent aged 75 to 84, and 32 percent aged 85 and older.

Women are more likely than men to develop Alzheimer disease because they live longer than men and their longer life expectancy increases the number of years during which they can develop it. It is estimated that Alzheimer disease triples the health-care costs of Americans 65 years of age and older (Alzheimer's Association, 2017). Because of the increasing

prevalence of Alzheimer disease, researchers have stepped up their efforts to discover the causes of the disease and to find more effective ways to treat it (Di Domenico & others, 2018; Lin, Zheng, & Zhang, 2018; Perneczky, 2018; Wolters & Arfan Iframe, 2018).

**Causes** Alzheimer disease involves a deficiency in the brain messenger chemical called acetylcholine, which plays an important role in memory (Kamal & others, 2017; Karthivashan & others, 2018; Kumar & others, 2018; Lewis & others, 2017). Also, as Alzheimer disease progresses, the brain shrinks and deteriorates (see Figure 4). This deterioration is characterized by the formation of *amyloid plaques* (dense deposits of protein that accumulate in the blood vessels) (Kocahan & Dogan, 2017; Morbelli & Baucknecht, 2018) and *neurofibrillary tangles* (twisted fibers that build up in neurons) (Villemagne & others, 2018; Xiao & others, 2017). Neurofibrillary tangles consist mainly of a protein called *tau* (Islam & others, 2017; Kuznetsov & Kuznetsov, 2018). Currently, there is considerable research interest in the roles that amyloid and tau play in Alzheimer disease (Michalicova & others, 2017; Park & Festini, 2018; Timmers & others, 2018).

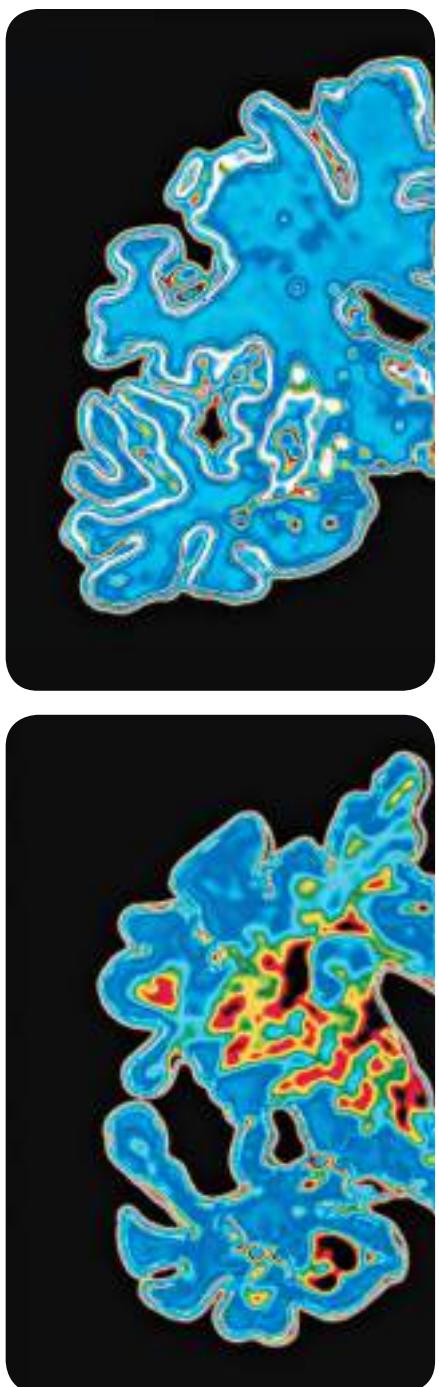

Until recently, neuroimaging of plaques and tangles had not been developed. However, recently new neuroimaging techniques have been developed that can detect these key indicators of Alzheimer disease in the brain (Park & Festini, 2018). This imaging breakthrough is providing scientists with an improved opportunity to identify the transition from healthy cognitive functioning to the earliest indication of Alzheimer disease (Basselerie & others, 2017; Das & others, 2018; Scarapicchia & others, 2018).

There also is increasing interest in the role that oxidative stress might play in Alzheimer disease (Butterfield, 2018; D'Acunto & others, 2018; Mantzavinos & others, 2017). Oxidative stress occurs when the body's antioxidant defenses don't cope with free radical attacks and oxidation in the body (Chhetri, King, & Gueven, 2018; Feitosa, 2018). Recall that free radical theory is a major theory of aging.

Although scientists are not certain what causes Alzheimer disease, age is an important risk factor and genes also are likely to play an important role (Del-Aguila & others, 2018; Lane-Donovan & Herz, 2017). The percentage of individuals with Alzheimer disease doubles every five years after the age of 65. A gene called *apolipoprotein E* (*ApoE*) is linked to increasing presence of plaques and tangles in the brain. Special attention has focused on an allele (an alternative form of a gene) labeled ApoE4, an allele that is a strong risk factor for Alzheimer disease (Carmona, Hardy, & Guerreiro, 2018; Fladby & others, 2017). More than 60 percent of individuals with Alzheimer disease have at least one ApoE4 allele, and females are more likely than males to have this allele (Dubal & Rogine, 2017; Riedel, Thompson, & Brinton, 2016). Indeed, the ApoE4 gene is the strongest genetic predictor of late-onset (65 years and older) Alzheimer disease (Carmona, Hardy, & Guerreiro, 2018; Dubal & Rogine, 2017). APP, PSEN1, and PSEN2 gene mutations are linked to early-onset Alzheimer disease (Carmona, Hardy, & Guerreiro, 2018).

Advances resulting from the Human Genome Project have recently resulted in identification of other genes that are risk factors for Alzheimer disease (Carmona, Hardy, & Guerreiro, 2018; Kawalia & others, 2017; Kumar & Reddy, 2018; Nativio & others, 2018; Tang & others, 2018). However, they are not as strongly linked to the disease as the ApoE4 gene (Costa & others, 2017; Gause & others, 2018; Shi & others, 2017).

Although individuals with a family history of Alzheimer disease are at greater risk, the disease is complex and likely caused by a number of factors. Recently, researchers have shown increasing interest in exploring how epigenetics may improve understanding of Alzheimer disease (Gangisetty, Cabrera, & Murugan, 2018; Sharma, Raghuraman, & Sajikumar, 2018). This interest especially has focused on DNA methylation, which we discussed in "Biological Beginnings." Recall that DNA methylation involves tiny atoms attaching themselves to the outside of a gene, a process that is increased through exercise and healthy diet but reduced by tobacco use (Marioni & others, 2018; Zaghloul & others, 2018). Thus, lifestyles likely interact with genes to influence Alzheimer disease (Kader, Ghai, & Mahraj, 2018; Shackleton, Crawford, & Bachmeier, 2017). For example, older adults with Alzheimer disease are more likely to have cardiovascular disease than are individuals who do not have Alzheimer disease (Rodrique & Bishof, 2017; Theobald, 2017; Wolters & others, 2018). Recently, a number of cardiac risk factors have been implicated in Alzheimer disease—obesity, smoking, atherosclerosis, hypertension, high cholesterol, lipids, and permanent atrial fibrillation (Falsetti & others, 2018; Hersi & others, 2017; Ihara & Washida, 2018; Karlsson & others, 2017). One of the best

**FIGURE 4**

©Alfred Pasieka/Science Source

strategies for intervening in the lives of people who are at risk for Alzheimer disease is to improve their cardiac functioning through diet, drugs, and exercise (Law & others, 2018; McLimans & others, 2017). One study of older adults found that those who exercised three or more times a week were less likely to develop Alzheimer disease over a six-year period than those who exercised less (Larson & others, 2006).

A recent meta-analysis of modifiable risk factors in Alzheimer disease found that some medical exposures (estrogen, statins, and nonsteroidal anti-inflammatory drugs) and some dietary factors (folate, vitamin E/C, and coffee) were linked to a reduced incidence of Alzheimer disease (Xu & others, 2015). Also in this meta-analysis, some preexisting diseases (atherosclerosis and hypertension) as well as depression increased the risk of developing Alzheimer disease. Further, cognitive activity and low-to-moderate alcohol use decreased the risk of developing Alzheimer disease.

**Early Detection and Drug Treatment** *Mild cognitive impairment (MCI)* represents a potential transitional state between the cognitive changes of normal aging and very early stages of Alzheimer disease and other dementias. MCI is increasingly recognized as a risk factor for Alzheimer disease (Cespedes & others, 2017; Gasquoine, 2018). Estimates indicate that as many as 10 to 20 percent of individuals 65 years of age and older have MCI (Alzheimer's Association, 2017). Many individuals with MCI do not go on to develop Alzheimer disease, but MCI is a risk factor for Alzheimer disease. One study revealed that individuals with mild cognitive impairment who developed Alzheimer disease had at least one copy of the ApoE4 gene (Alegret & others, 2014). In this study, the extent of memory impairment was the key factor linked to the speed of decline from mild cognitive impairment to Alzheimer disease.

Distinguishing between individuals who merely have age-associated declines in memory and those with MCI is difficult, as is predicting which individuals with MCI will subsequently develop Alzheimer disease (Eliassen & others, 2017; Mendoza Laiz & others, 2018). A research review concluded that fMRI measurement of neuron loss in the medial temporal lobe is a predictor of memory loss and eventually dementia (Vellas & Aisen, 2010). Further, another study revealed that amyloid beta—a protein fragment that forms plaques in the brain—was present in the spinal fluid of approximately 75 percent of the individuals with mild cognitive impairment (De Meyer & others, 2010). Every one of the older adults with mild cognitive impairment who had the amyloid beta in their spinal fluid developed Alzheimer disease within five years.

**Drug Treatment of Alzheimer Disease** Five drugs have been approved by the U.S. Food and Drug Administration (FDA) for the treatment of Alzheimer disease (Almeida, 2018). Three of the medications, Aricept (donepezil), Razadyne (galantamine), and Exelon (rivastigmine), are cholinesterase inhibitors designed to improve memory and other cognitive functions by increasing levels of acetylcholine in the brain (Gareri & others, 2017). A fourth drug, Namenda (memantine), regulates the activity of glutamate, which is involved in processing information. Namzaric, a combination of memantine and donepezil, is the fifth approved medicine to treat Alzheimer disease; this medicine is designed to improve cognition and overall mental ability (Almeida, 2018). A research review concluded that cholinesterase inhibitors do not reduce progression to dementia from mild cognitive impairment (Masoodi, 2013). Also, keep in mind that the current drugs used to treat Alzheimer disease only slow the downward progression of the disease; they do not address its cause (Boccardi & others, 2017). Also, no drugs have yet been approved by the Food and Drug Administration (FDA) for the treatment of MCI (Alzheimer's Association, 2017).

**Caring for Individuals with Alzheimer Disease** A special concern is caring for Alzheimer patients (Callahan & others, 2017; Merlo & others, 2018; Wolff & others, 2018). Health-care professionals emphasize that the family can be an important support system for the Alzheimer patient, but this support can have costs for family members who become emotionally and physically drained by the extensive care required by a person with Alzheimer disease (Wawrzicznny & others, 2017; White & others, 2018). A recent study confirmed that family caregivers' health-related quality of life in the first three years after they began caring for a family member with Alzheimer disease deteriorated more than their same-age and same-gender counterparts who were not caring for an Alzheimer patient (Valimaki & others, 2016). Another study compared family members' perception of caring for someone with Alzheimer disease, cancer, or schizophrenia (Papastavrou & others, 2012). In this study, the highest perceived burden was reported for Alzheimer disease.

## *connecting* with careers

### Jan Weaver, Director of the Alzheimer's Association of Dallas

Dr. Weaver joined the Alzheimer's Association, Greater Dallas Chapter, as director of services and education in 1999. Prior to that time, she served as associate director of education for the Texas Institute for Research and Education on Aging and director of the National Academy for Teaching and Learning About Aging at the University of North Texas. As a gerontologist, Weaver plans and develops services and educational programs that address patterns of human development related to aging. Among the services that Weaver supervises at the Alzheimer's Association are a resource center and helpline, a family assistance program, a care program, support groups, referrals and information, educational conferences, and community seminars.

Weaver recognizes that people of all ages should have an informed and balanced view of older adults that helps them perceive aging as a process of growth and fulfillment rather than a process of decline and dependency. Weaver earned her Ph.D. in sociology, with an emphasis in gerontology, from the University of Texas.

*Respite care* (services that provide temporary relief for those who are caring for individuals with disabilities, individuals with illnesses, or the elderly) has been developed to help people who have to meet the day-to-day needs of Alzheimer patients. This type of care provides an important break from the burden of providing chronic care (Tretteteig, Vatne, & Rokstad, 2017; Washington & Tachman, 2017; Wolff & others, 2018).

There are many career opportunities that involve working with individuals who have Alzheimer disease. To read about the work of a director of an Alzheimer association, see *Connecting with Careers*.

**Parkinson Disease** Another type of dementia is **Parkinson disease**, a chronic, progressive disease characterized by muscle tremors, slowing of movement, and partial facial paralysis. Parkinson disease is triggered by degeneration of dopamine-producing neurons in the brain (Chung & others, 2018; Goldstein & others, 2018; Rastedt, Vaughan, & Foster, 2017). Dopamine is a neurotransmitter that is necessary for normal brain functioning. Why these neurons degenerate is not known.

The main treatment for Parkinson disease involves administering drugs that enhance the effect of dopamine (dopamine agonists) in the disease's earlier stages and later administering the drug L-dopa, which is converted by the brain into dopamine (Juhasz & others, 2017; Radhakrishnan & Goyal, 2018). However, it is difficult to determine the correct level of dosage of L-dopa, and the drug loses efficacy over time (Nomoto & others, 2009).

Another treatment for advanced Parkinson disease is deep brain stimulation (DBS), which involves implantation of electrodes within the brain (Singh & others, 2018; Stefani & others, 2017). The electrodes are then stimulated by a pacemaker-like device. Recent studies indicated that deep brain stimulation may provide benefits for individuals with Parkinson disease (Krishnan & others, 2018; Odekerken & others, 2016). Other recent studies indicate that certain types of dance, such as the tango, may improve the movement skills of individuals with Parkinson disease (Batson, Hugenschmidt, & Soriano, 2016). Stem cell transplantation and gene therapy also offer hope for treating the disease (Choi & others, 2017; Parmar, 2018; Xu & others, 2017).

Older adults who are depressed, have a dementia, or have another mental disorder, may need mental health treatment (Haigh & others, 2017). To read about this topic, see *Connecting Development to Life*.

Muhammad Ali, considered one of the world's most influential sports figures, had Parkinson disease.

# connecting development to life

## Meeting the Mental Health Needs of Older Adults

Older adults receive disproportionately fewer mental health services than young or middle-aged adults (Sanglier & others, 2015). One estimate is that only 2.7 percent of all clinical services provided by psychologists go to older adults, although individuals aged 65 and over make up more than 11 percent of the population. Psychotherapy can be expensive. Although reduced fees and sometimes no fee can be arranged in public hospitals for older adults from low-income backgrounds, many older adults who need psychotherapy do not get it (Brown & Menec, 2018; Kietzman & others, 2018; Haigh & others, 2017). It has been said that psychotherapists like to work with young, attractive, verbal, intelligent, and successful clients (called YAVISes) rather than those who are quiet, ugly, old, institutionalized, and different (called QUOIDs). Psychotherapists have been accused of failing to see older adults because they perceive that older adults have a poor prognosis for therapy success; they do not feel they have adequate training to treat older adults, who may have special problems requiring special treatment; and they may have stereotypes that label older adults as low-status and unworthy recipients of treatment (Virnig & others, 2004). Also, many older adults do not seek mental health treatment because of a fear that they will be stigmatized or because of a lack of understanding about the nature of mental health treatment and care.

How can we better meet the mental health needs of older adults? First, mental health professionals must be encouraged to include greater numbers of older adults in their client lists, and older adults must be convinced that they can benefit from therapy (Knight & Kellough, 2013; Nelson & Purtle, 2018; Olfson & others, 2018). Second, we must make mental health care affordable. For example, Medicare continues to fall short of providing many mental health services for older adults, especially for those in need of long-term care (Knight & Lee, 2007).

Margaret Gatz (right) has been a crusader for better mental health treatment of older adults. She believes that mental health professionals need to be encouraged to include greater numbers of older adults in their client lists and that we need to better educate the elderly about how they can benefit from therapy. *What are some common mechanisms of change that can be used to improve the mental health of older adults?*

Courtesy of Dr. Margaret Gatz

*Earlier in this chapter, we discussed stereotypes and ageism with regard to older adults in the workforce. How are those concepts related to what you just read in this interlude?*

### Review Connect Reflect

**LG4** Describe mental health problems in older adults.

#### Review

- What is the nature of depression in older adults?
- What are dementia, Alzheimer disease, and Parkinson disease like in older adults?

#### Connect

- What are some differences in how depression is characterized in adolescence as opposed to late adulthood?

#### Reflect Your Own Personal Journey of Life

- Have any of your relatives experienced mental health problems as older adults? If so, what were these mental health problems? If they have experienced mental health problems, what were the likely causes of the problems?

## 5 Religion and Spirituality

LG5

Explain the role of religion and spirituality in the lives of older adults.

Earlier we discussed religion, spirituality, and meaning in life with a special focus on middle age, including links between religion/spirituality and health. Here we will continue our exploration of religion and spirituality by considering their importance in the lives of many older adults.

In many societies around the world, older adults are the spiritual leaders in their churches and communities. For example, in the Catholic Church more popes have been elected in their eighties than in any other 10-year period of the human life span.

The religious patterns of older adults have increasingly been studied (Krause & Hayward, 2016). A longitudinal study found that religious service attendance was stable in middle adulthood, increased in late adulthood, then declined later in the older adult years (Hayward & Krause, 2013b). A research review concluded that individuals with a stronger spiritual/religious orientation were more likely to live longer (Lucchetti, Lucchetti, & Koenig, 2011). Also, in a recent study of older adults, those who regularly attended religious services lived longer than their counterparts who did not attend these services (Idler & others, 2017).

Individuals over 65 years of age are more likely than younger people to say that religious faith is the most significant influence in their lives, that they try to put religious faith into practice, and that they attend religious services (Gallup & Bezilla, 1992). A study of more than 500 African Americans 55 to 105 years of age revealed that they had a strong identification with religious institutions and high levels of attendance and participation in religious activities (Williams, Keigher, & Williams, 2012). And a Pew poll found that belief in God was higher in older adulthood than in any other age period (Pew Forum on Religion and Public Life, 2008). Further, a recent study revealed that older women had higher levels of spirituality than did older men (Bailly & others, 2018).

Is religion related to a sense of well-being and life satisfaction in old age? In a recent study of older adults, secure attachment to God was linked to an increase in optimism and self-esteem in the future (Kent, Bradshaw, & Uecker, 2018). In another study, older adults who derived a sense of meaning in life from religion had higher levels of life satisfaction, self-esteem, and optimism (Krause, 2003). Further, a recent study of older adults revealed that religious service attendance was associated with a higher level of resilience in life and lower levels of depression (Manning & Miles, 2018). And in a recent study of Korean older adults, higher levels of religious/spiritual coping were linked to lower levels of depressive symptoms (Lee & others, 2017). Further, a recent study of Latinos found that lack of religiosity was associated with elevated anxiety and depressive symptoms in older adults but not in young and middle-aged adults (Leman & others, 2018).

Religion and spirituality can meet some important psychological needs in older adults, helping them to face impending death, to find and maintain a sense of meaning in life, and to accept the inevitable losses of old age (Krause & Hayward, 2016; Park & others, 2016, 2017). Socially, the religious community can serve many functions for older adults, such as social activities, social support, and the opportunity to assume teaching and leadership roles (Krause, 2012). One study revealed that over a period of seven years, older adults who attended church regularly increased the amount of emotional support they gave and received but decreased the amount of tangible support they gave and received (Hayward & Krause, 2013a).

During late adulthood, many individuals increasingly engage in prayer. *How might this be linked with longevity?*

### Review Connect Reflect

LG5 Explain the role of religion and spirituality in the lives of older adults.

#### Review

- What are some characteristics of religion and spirituality in older adults?

#### Connect

- Prayer and meditation may reduce stress and dampen the body's production of stress hormones.

#### developmental connection

##### Religion and Spirituality

Meaning-making coping involves drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of chronic stress such as when a loved one dies. Connect to "Physical and Cognitive Development in Middle Adulthood."

Why is this especially important in the aging process?

#### Reflect Your Own Personal Journey of Life

- Do you think you will become more or less religious as an older adult than you are now? Explain.

## topical connections *looking forward*

In the next chapter, you will read about a number of theories that seek to explain older adults' socioemotional development, including Erikson's final stage (integrity versus despair). Older adults become more selective than middle-aged adults about the people they want to spend time with. There is considerable diversity in older adults' lifestyles, and an increasing number of older adults cohabit. Social support is especially important in older adults' lives and is linked to their physical and mental health. An important aspect of late adulthood is not dwelling too extensively on the negative aspects of aging but rather pursuing the key dimensions of successful aging.

## reach your learning goals

# Cognitive Development in Late Adulthood

### 1 Cognitive Functioning in Older Adults

LG1

Describe the cognitive functioning of older adults.

Multidimensionality and Multidirectionality

- Cognitive mechanics (the neurophysiological architecture, including the brain) are more likely to decline in older adults than are cognitive pragmatics (the culture-based software of the mind). Speed of processing declines in older adults. Older adults' attention declines more on complex than simple tasks. Regarding memory, in late adulthood explicit memory declines more than implicit memory; episodic memory declines more than semantic memory; working memory also declines. Components of executive function—such as cognitive control and working memory—decline in late adulthood. Decision making is reasonably well preserved in older adults. Recently, there has been increased interest in the role of metacognition and mindfulness in improving older adults' cognitive functioning.
- Wisdom is expert knowledge about the practical aspects of life that permits excellent judgment about important matters. Baltes and his colleagues have found that high levels of wisdom are rare, the time frame of late adolescence and early adulthood is the main window for wisdom to emerge, factors other than age are critical for wisdom to develop, and personality-related factors are better predictors of wisdom than cognitive factors such as intelligence.
- Successive generations of Americans have been better educated. Education is positively correlated with scores on intelligence tests. Older adults may return to college for a number of reasons. Recent generations have had work experiences that include a stronger emphasis on cognitively oriented labor. The increased emphasis on information processing in jobs likely enhances an individual's intellectual abilities. Poor health is related to decreased performance on intelligence tests by older adults. Exercise is linked to higher cognitive functioning in older adults.
- Researchers are finding that older adults who engage in cognitive activities, especially challenging ones, have higher cognitive functioning than those who don't use their cognitive skills.
- Two main conclusions can be derived from research on training cognitive skills in older adults: (1) training can improve the cognitive skills of many older adults, and (2) there is some loss in plasticity in late adulthood.

Education, Work,  
and Health

Use It or Lose It

Training Cognitive Skills

## Cognitive Neuroscience and Aging

- There has been considerable recent interest in the cognitive neuroscience of aging that focuses on links among aging, the brain, and cognitive functioning. This field especially relies on fMRI and PET scans to assess brain functioning while individuals are engaging in cognitive tasks. One of the most consistent findings in this field is a decline in the functioning of specific regions in the prefrontal cortex in older adults and links between this decline and poorer performance on tasks involving complex reasoning, working memory, and episodic memory.

## 2 Language Development

LG2

Characterize changes in language skills in older adults.

- For many individuals, knowledge of words and word meanings continues unchanged or may even improve in late adulthood. However, some decline in language skills may occur in retrieval of words for use in conversation, comprehension of speech, phonological skills, and some aspects of discourse. These changes in language skills in older adults likely occur as a consequence of declines in hearing or memory, a reduced speed of processing information, or disease.

## 3 Work and Retirement

LG3

Discuss aging and adaptation to work and retirement.

Work

Retirement in the United States and in Other Countries

Adjustment to Retirement

- An increasing number of older adults are continuing to work past 65 years of age, compared with their counterparts in past decades. An important change in older adults' work patterns is the increase in part-time work. Some individuals continue a life of strong work productivity throughout late adulthood.
- A retirement option for older workers is a late-twentieth-century phenomenon in the United States. Americans are more likely to continue working in their seventies than are workers in other countries.
- The pathways individuals follow when they reach retirement age today are less clear than in the past. Those who adjust best to retirement are individuals who are healthy, have adequate income, are active, are better educated, have an extended social network of friends and family, and are satisfied with their lives before they retire.

## 4 Mental Health

LG4

Describe mental health problems in older adults.

Depression

Dementia, Alzheimer Disease, and Other Afflictions

- Depression has been called the "common cold" of mental disorders. However, a majority of older adults with depressive symptoms never receive mental health treatment.
- Dementia is a global term for any neurological disorder in which the primary symptoms involve a deterioration of mental functioning. Alzheimer disease is by far the most common dementia. This progressive, irreversible disorder is characterized by gradual deterioration of memory, reasoning, language, and eventually physical functioning. Special efforts are being made to discover the causes of Alzheimer disease and effective treatments for it. The increase in amyloid plaques and neurofibrillary tangles in Alzheimer patients may hold important keys to improving our understanding of the disease. Alzheimer disease is characterized by a deficiency in acetylcholine, a brain chemical that affects memory. Also, in Alzheimer disease the brain shrinks and deteriorates as plaques and tangles form. Important concerns are the financial implications of caring for Alzheimer patients and the burdens placed on caregivers. In addition to Alzheimer disease, another type of dementia is Parkinson disease.

## 5 Religion and Spirituality

LG5

Explain the role of religion and spirituality in the lives of older adults.

- Many older adults are spiritual leaders in their church and community. Religious interest increases in old age and is related to a sense of well-being in the elderly.

# SOCIOEMOTIONAL DEVELOPMENT IN LATE ADULTHOOD

## chapter outline

### ① Theories of Socioemotional Development

**Learning Goal 1** Discuss four theories of socioemotional development and aging

- Erikson's Theory
- Activity Theory
- Socioemotional Selectivity Theory
- Selective Optimization with Compensation Theory

### ② Personality, the Self, and Society

**Learning Goal 2** Describe links between personality and mortality, and identify changes in the self and society in late adulthood

- Personality
- The Self and Society
- Older Adults in Society

### ③ Families and Social Relationships

**Learning Goal 3** Characterize the families and social relationships of aging adults

- Lifestyle Diversity
- Attachment
- Older Adult Parents and Their Adult Children
- Great-Grandparenting
- Friendship
- Social Support and Social Integration
- Altruism and Volunteering

### ④ Ethnicity, Gender, and Culture

**Learning Goal 4** Summarize how ethnicity, gender, and culture are linked with aging

- Ethnicity
- Gender
- Culture

### ⑤ Successful Aging

**Learning Goal 5** Explain how to age successfully

**B**ob Cousy was a star player on Boston Celtics teams that won numerous National Basketball Association championships. In recognition of his athletic accomplishments, Cousy was honored by ESPN as one of the top 100 athletes of the twentieth century. After he retired from basketball, he became a college basketball coach and then into his seventies was a broadcaster of Boston Celtics basketball games. Cousy has retired from broadcasting but continues to play golf and tennis on a regular basis. He has a number of positive social relationships, including his marriage, children and grandchildren, and many friends. In 2013, after 63 years of marriage, Cousy said a last goodbye to his wife, who had dementia and died. After she developed dementia, he cared for her in their home on a daily basis as she slowly succumbed to the deterioration of her mind and body. Since her death, when he goes to bed each night, he tells her he loves her (Williamson, 2013).

As is the case with many famous people, Cousy's awards reveal little about his personal life and contributions. In addition to his extensive provision of care for his wife in her last years, two other examples illustrate his humanitarian efforts to help others (McClellan, 2004). First, when Cousy played for the Boston Celtics, his African American teammate, Chuck Cooper, was refused a room on a road trip because of his race. Cousy expressed anger to his coach about the situation and then accompanied an appreciative Cooper on a train back to Boston. Second, the Bob Cousy Humanitarian Fund "honors individuals who have given their lives to using the game of basketball as a medium to help others" (p. 4). The Humanitarian Fund reflects Cousy's motivation to care for others, be appreciative and give something back, and make the world less self-centered.

# topical connections *looking back*

Middle adulthood is a time when individuals become more conscious of the young-old polarity in life and the shrinking amount of time left in their lives. And it is a time when individuals seek to transmit something meaningful to the next generation. The concept of midlife crisis has been exaggerated; when people do experience this crisis, it often is linked to negative life events. Stability of personality peaks in middle adulthood, and marital satisfaction often increases at this time. Many middle-aged adults become grandparents, and the middle-aged generation plays a key role in intergenerational relationships, with middle-aged women especially connecting generations.

## preview

Bob Cousy's life as an older adult reflects some of the themes of socioemotional development in older adults that we will discuss in this chapter. These include the important role that being active plays in life satisfaction, the need to adapt to changing skills, and the ways in which close relationships with friends and family contribute to an emotionally fulfilling life.

### 1 Theories of Socioemotional Development

LG1

Discuss four theories of socioemotional development and aging.

Erikson's Theory

Activity Theory

Socioemotional Selectivity Theory

Selective Optimization with Compensation Theory

We will explore four main theories that focus on socioemotional development in late adulthood: Erikson's theory, activity theory, socioemotional selectivity theory, and selective optimization with compensation theory.

#### ERIKSON'S THEORY

We initially discussed Erik Erikson's (1968) eight stages of the human life span in the "Introduction" chapter. In other chapters we examined Erikson's stages in greater detail as we explored different periods of development. Here we will discuss his final stage.

**Integrity Versus Despair** **Integrity versus despair** is Erikson's eighth and final stage of development, which individuals experience during late adulthood. This stage involves reflecting on the past and either piecing together a positive review or concluding that one's life has not been well spent. Through many different routes, the older adult may have developed a positive outlook in each of the preceding periods. If so, retrospective glances and reminiscences will reveal a picture of a life well spent, and the older adult will be satisfied (integrity). But if the older adult resolved one or more of the earlier stages in a negative way (being socially isolated in early adulthood or stagnating in middle adulthood, for example), retrospective evaluations of the total worth of his or her life might be negative (despair). Figure 1 portrays how positive resolutions of Erikson's eight stages can culminate in wisdom and integrity for older adults.

**Life Review** Life review is prominent in Erikson's final stage of integrity versus despair. Life review involves looking back at one's life experiences, evaluating them, interpreting them, and often reinterpreting them (Hitchcock & others, 2017; Zhang & Ho, 2017). A leading expert on aging, Robert Butler, provided this perspective on life review: ". . . there are chances for pain, anger, guilt, and grief, but there are also opportunities for resolution and celebration, for affirmation and hope, for reconciliation and personal growth" (Butler, 2007, p. 72).

#### developmental connection

##### Erikson's Theory

Erikson's other two adult stages are intimacy versus isolation (early adulthood) and generativity versus stagnation (middle adulthood). Connect to "Socioemotional Development in Early Adulthood" and "Socioemotional Development in Middle Adulthood."

**integrity versus despair** Erikson's eighth and final stage of development, which individuals experience in late adulthood. This involves reflecting on the past and either piecing together a positive review or concluding that one's life has not been well spent.

## FIGURE 1

### ERIKSON'S VIEW OF HOW POSITIVE RESOLUTION OF THE EIGHT STAGES OF THE HUMAN LIFE SPAN CAN CULMINATE IN WISDOM AND INTEGRITY

**IN OLD AGE.** In Erikson's view, each stage of life is associated with a particular psycho-social conflict and a particular resolution. In this chart, Erikson describes how the issue from each of the earlier stages can mature into the many facets of integrity and wisdom in old age.

Conflict and Resolution	Culmination in Old Age
<b>Old age</b> Integrity vs. despair: wisdom	Existential identity; a sense of integrity strong enough to withstand physical disintegration.
<b>Middle adulthood</b> Generativity vs. stagnation: care	Caring for others, and empathy and concern.
<b>Early adulthood</b> Intimacy vs. isolation: love	Sense of complexity of relationships; value of tenderness and loving freely.
<b>Adolescence</b> Identity vs. confusion: fidelity	Sense of complexity of life; merger of sensory, logical, and aesthetic perception.
<b>School age</b> Industry vs. inferiority: competence	Humility; acceptance of the course of one's life and unfulfilled hopes.
<b>Early childhood</b> Initiative vs. guilt: purpose	Humor; empathy; resilience.
<b>Toddlerhood</b> Autonomy vs. shame: will	Acceptance of the cycle of life, from integration to disintegration.
<b>Infancy</b> Basic trust vs. mistrust: hope	Appreciation of interdependence and relatedness.

Butler (2007) states that the life review is set in motion by looking forward to death. Sometimes the life review proceeds quietly; at other times it is intense, requiring considerable work to achieve some sense of personality integration. The life review may be observed initially in stray and insignificant thoughts about oneself and one's life history. These thoughts may continue to emerge in brief intermittent spurts or become essentially continuous. One 76-year-old man commented, "My life is in the back of my mind. It can't be any other way. Thoughts of the past play on me. Sometimes I play with them, encouraging and savoring them; at other times I dismiss them."

Life reviews can include sociocultural dimensions, such as culture, ethnicity, and gender. Life reviews also can include interpersonal, relationship dimensions, including sharing and intimacy with family members or friends (Korte & others, 2014). And life reviews can include personal dimensions, which might involve the creation and discovery of meaning and coherence. These personal dimensions might unfold in such a way that the pieces do or don't make sense to the older adult. The life review might result in increased meaning in life and mastery, but it also might revive bitterness and negative thoughts (Korte, Westerhof, & Bohlmeijer, 2012). In the final analysis, each person's life review is to some degree unique.

One aspect of life review involves identifying and reflecting on not only the positive aspects of one's life but also on regrets as part of developing mature levels of wisdom and self-understanding (Choi & Jun, 2009). The hope is that by examining not only the positive aspects of one's life but also what one has regretted doing (or not doing), a more accurate vision of the complexity of one's life and possibly increased life satisfaction will be attained (King & Hicks, 2007).

When working with older clients, some clinicians use *reminiscence therapy*, which involves discussing past activities and experiences with another individual or group (Woods & others, 2018; Wu & others, 2018). The therapy may include the use of photographs, familiar items, and video/audio recordings. Researchers have found that reminiscence therapy improves the mood and quality of older adults, including those with dementia (Han, J. W., & others, 2017; Siverova & Buzgova, 2018; Woods & others, 2018; Yen & Lin, 2018). A recent study with older adults who had dementia found that reminiscence therapy reduced their depressive symptoms and improved their self-acceptance and positive relations with others (Gonzalez & others, 2015). Also, a meta-analysis of 128 studies found that through reminiscence therapy clients attained a higher sense of integrity (based on Erikson's concept of integrity versus despair) (Pinquart & Forstmeier, 2012). One study with elderly institutionalized adults found that 8 weeks of group reminiscence therapy resulted in increased self-esteem, life satisfaction, and psychological well-being, and reduced depression (Melendez-Moral & others, 2013). Further, a variation of reminiscence therapy, *instrumental* reminiscence therapy (recalling the times one coped with stressful circumstances and analyzing what it took to adapt in those contexts), improved the adaptive

What characterizes a life review in late adulthood?

©PeopleImages/Getty Images

ability and resilience of older adults in coping with adverse situations (Melendez & others, 2015). A recent study found that an instrumental reminiscence intervention improved the coping skills of older adults (Satorres & others, 2018). In another version of reminiscence therapy, *attachment-focused* reminiscence therapy reduced depressive symptoms, perceived stress, and emergency room visits in older African Americans (Sabir & others, 2016).

## ACTIVITY THEORY

**Activity theory** states that the more active and involved older adults are, the more likely they are to be satisfied with their lives. Researchers have found strong support for activity theory, beginning in the 1960s and continuing into the twenty-first century (Antonucci & Webster, 2019; Duggal & others, 2018; Lim & others, 2017; Mella & others, 2017; Neugarten, Havighurst, & Tobin, 1968; Strandberg, 2019; Walker, 2019). These researchers have found that when older adults are active, energetic, and productive, they age more successfully and are happier than if they disengage from society (Walker, 2019). A recent study found that older adults who increased their leisure-time activity were three times more likely to have a slower progression to having a functional disability (Chen & others, 2016). Also, a study of Canadian older adults revealed that those who were more physically active had higher life satisfaction and greater social interaction than their physically inactive counterparts (Azagba & Sharaf, 2014). And a recent study indicated that an activity-based lifestyle was linked to lower levels of depression in older adults (Juang & others, 2018). Activity theory suggests that many individuals will achieve greater life satisfaction if they continue their middle-adulthood roles into late adulthood. If these roles are stripped from them (as in early retirement), it is important for them to find substitute roles that keep them active and involved.

Should adults stay active or become more disengaged as they become older? Explain.  
©Chuck Savage/Corbis/Getty Images

## SOCIOEMOTIONAL SELECTIVITY THEORY

**Socioemotional selectivity theory** states that adults become more selective about their social networks as they grow older. Because they place a high value on emotional satisfaction, older adults spend more time with familiar individuals with whom they have had rewarding relationships. Developed by Laura Carstensen (1998, 2006, 2008, 2009, 2011, 2014, 2015a, b, 2016; Carstensen & DeLiema, 2018; Carstensen & others, 2015), this theory states that older adults deliberately withdraw from social contact with individuals peripheral to their lives while maintaining or increasing contact with close friends and family members with whom they have had enjoyable relationships. This selective narrowing of social interaction maximizes positive emotional experiences and minimizes emotional risks as individuals become older. The fact that older adults have a decreasing number of years to live likely influences them to place more emphasis on prioritizing meaningful relationships (Moss & Wilson, 2018; Segerstrom & others, 2016).

Socioemotional selectivity theory challenges the stereotype that the majority of older adults are in emotional despair because of their social isolation (Carstensen, 2011, 2014, 2015a, b). Rather, older adults consciously choose to decrease the total number of their social contacts in favor of spending increasing time in emotionally rewarding moments with friends and family. That is, they systematically refine their social networks so that available social partners satisfy their emotional needs (Carstensen & others, 2015; Sims, Hogan, & Carstensen, 2015).

Is there research evidence to support life-span differences in the composition of social networks? Researchers have found that older adults have far smaller social networks than younger adults do (Charles & Carstensen, 2010; Wrzus & others, 2013). In one study of individuals 69 to 104 years of age, the oldest participants had fewer peripheral social contacts than the relatively younger participants but about the same number of close emotional relationships (Lang & Carstensen, 1994). In a later study of individuals from 18 to 94 years of age, older adults had fewer peripheral social contacts but retained close relationships with people who provided them with emotional support (English & Carstensen, 2014).

However, in the Sightlines Project, a recent large-scale examination of healthy living in different age groups conducted by the Stanford Center on Longevity, social engagement with individuals and communities appeared to be weaker today than it was 15 years ago for 55- to 64-year-olds (Parker, 2016). Many of these individuals, who are about to reach retirement age, have weaker relationships with spouses, partners, family, friends, and neighbors than did their counterparts of 15 years ago. The Sightlines Project (2016) recommends the following interventions to increase the social engagement of older adults: employer wellness programs that

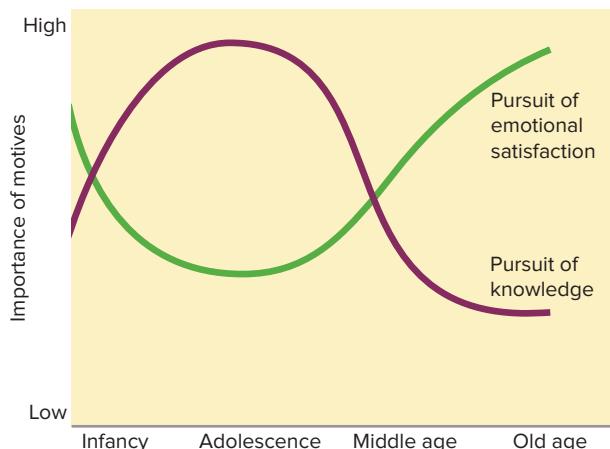

Laura Carstensen (right), in a caring relationship with an older woman. Her theory of socioemotional selectivity is gaining recognition as an important perspective on aging.

Courtesy of Dr. Laura Carstensen

**activity theory** The theory that the more active and involved older adults are, the more likely they are to be satisfied with their lives.

**socioemotional selectivity theory** The theory that older adults become more selective about their social networks. Because they place a high value on emotional satisfaction, older adults often spend more time with familiar individuals with whom they have had rewarding relationships.

**FIGURE 2**

**IDEALIZED MODEL OF SOCIOEMOTIONAL SELECTIVITY THROUGH THE LIFE SPAN.** In Carstensen's theory of socioemotional selectivity, the motivation to reach knowledge-related and emotion-related goals changes across the life span.

strengthen support networks, environmental design that improves neighborhood and community life, technologies that improve personal relationships, and opportunities for volunteerism.

Socioemotional selectivity theory also focuses on the types of goals that individuals are motivated to achieve (Sims, Hogan, & Carstensen, 2015). It states that two important classes of goals are (1) knowledge-related and (2) emotional. This theory emphasizes that the trajectory of motivation for knowledge-related goals starts relatively high in the early years of life, peaks in adolescence and early adulthood, and then declines during middle and late adulthood (see Figure 2). The emotional trajectory is high during infancy and early childhood, declines from middle childhood through early adulthood, and increases in middle and late adulthood. In a recent commentary, Laura Carstensen (2016) commented that when older adults focus on emotionally meaningful goals, they are more satisfied with their lives, feel better, and experience fewer negative emotions.

One of the main reasons given for these changing trajectories in knowledge-related and emotion-related goals involves the perception of time (Carstensen, 2006). When time is perceived as open-ended, as it is when individuals are younger, people are more strongly motivated to pursue information, even at the cost of emotional satisfaction. But as older adults perceive that they have less time left in their lives, they are motivated to spend more time pursuing emotional satisfaction (Kaszniak & Menchola, 2012; Paul, 2019).

Are older adults more emotionally satisfied than younger adults? In general, compared with younger adults, the feelings of older adults mellow. Emotional life is on a more even keel, with fewer highs and lows. It may be that although older adults have less extreme joy, they have more contentment, especially when they are connected in positive ways with friends and family. Compared with younger adults, older adults react less strongly to negative circumstances, are better at ignoring irrelevant negative information, and remember more positive than negative information (Mather, 2012).

Researchers have found that positive emotions increase and negative emotions (except for sadness) decrease from 50 years of age through the mid-eighties (Stone & others, 2010). In this study, a pronounced decline in anger occurred from the early twenties and sadness was essentially unchanged from the early twenties through the mid-eighties. Another study found that aging was linked to more positive overall well-being and greater emotional stability (Carstensen & others, 2011). In this study, adults who experienced more positive than negative emotions were more likely to remain alive over a 13-year period. Other research also indicates that happier people live longer (Frey, 2011). And in a recent study, older adults reacted with less anger about a personal memory than younger adults did (Kunzmann & others, 2017). Further, in another study, older men showed more engagement with highly positive contexts than did younger men (Martins & others, 2018). Also, in a recent meta-analysis of 72 studies of more than 19,000 individuals in 19 countries, it was concluded that emotional experiences are more positive in the lives of older adults than in the lives of younger adults (Laureiro-Martinez, Trujillo, & Unda, 2017). Also, in this review, it was concluded that older adults focus less on negative events in their past than younger adults do. Thus, the emotional life of older adults is more positive and less negative than stereotypes suggest (Carstensen, 2016).

## SELECTIVE OPTIMIZATION WITH COMPENSATION THEORY

Selective optimization with compensation theory states that successful aging depends on three main factors: selection, optimization, and compensation (SOC). The theory describes how people can produce new resources and allocate them effectively to the tasks they want to master (Alonso-Fernandez & others, 2016; Freund, Nikitin, & Riediger, 2013; Nikitin & Freund, 2019; Riediger, Li, & Lindenberger, 2006; Staudinger & Jacobs, 2010). *Selection* is based on the concept that older adults have a reduced capacity and loss of functioning, which require a reduction in performance in most life domains. *Optimization* suggests that it is possible to maintain performance in some areas through continued practice and the use of new technologies. *Compensation* becomes relevant when life tasks require a level of capacity beyond the current level of the older

**selective optimization with compensation theory** The theory that successful aging is related to three main factors: selection, optimization, and compensation.

adult's performance potential. Older adults especially need to compensate in circumstances involving high mental or physical demands, such as when thinking about and memorizing new material in a very short period of time, reacting quickly when driving a car, or moving quickly. When older adults develop an illness, the need for compensation is obvious.

Selective optimization with compensation theory was proposed by Paul Baltes and his colleagues (Baltes, 2003; Baltes, Lindenberger, & Staudinger, 2006). They describe the life of the late Arthur Rubinstein to illustrate their theory. When he was interviewed at 80 years of age, Rubinstein said that three factors were responsible for his ability to maintain his status as an admired concert pianist into old age. First, he mastered the weakness of old age by reducing the scope of his performances and playing fewer pieces (which reflects selection). Second, he spent more time at practice than earlier in his life (which reflects optimization). Third, he used special strategies, such as slowing down before fast segments, thus creating a perception of faster playing (which reflects compensation).

The process of selective optimization with compensation is likely to be effective whenever people pursue successful outcomes (Baethge, Muller, & Rigotti, 2016; Freund & Hennecke, 2015; Freund, Nikitin, & Riediger, 2013; Marquez-Gonzalez, Cheng, & Losada, 2019; Miller, 2016; Nikitin & Freund, 2019; Staudinger & Jacobs, 2010). In a recent study of individuals from 22 to 94 years of age, on days when middle-aged and older adults, as well as individuals who were less healthy, used more selective optimization with compensation strategies, they reported a higher level of happiness (Teshale & Lachman, 2016).

SOC is attractive to researchers who study aging because it makes explicit how individuals can manage and adapt to losses (Nikitin & Freund, 2019). By using SOC, older adults can continue to lead satisfying lives, although in a more restricted manner. In a recent study of 22- to 94-year-olds, middle-aged adults had the highest daily use of SOC, although older adults also showed high SOC use if they had a high level of cognitive resources (Robinson, Rickenbach, & Lachman, 2016).

Loss is a common dimension of old age, although there are wide variations in the nature of the losses involved. Because of these individual variations, the specific form of selection, optimization, and compensation will likely vary, depending on the person's life history, pattern of interests, values, health, skills, and resources. To read about some strategies for effectively engaging in selective optimization with compensation, see *Connecting Development to Life*.

In Baltes' view (2003; Baltes, Lindenberger, & Staudinger, 2006), the selection of domains and life priorities is an important aspect of development. Life goals and priorities likely vary across the life course for most people. For many individuals, it is not just the sheer attainment of goals, but rather the attainment of *meaningful* goals, that makes life satisfying.

## connecting development to life

### Strategies for Effectively Engaging in Selective Optimization with Compensation

What are some good strategies that aging adults can engage in to attain selective optimization with compensation? According to Paul Baltes and his colleagues (Baltes, Lindenberger, & Staudinger, 2006; Freund & Baltes, 2002), the following strategies are likely to be effective.

#### Selection Strategies

- Focus on the most important goal at a particular time.
- Think about what you want in life and commit yourself to one or two major goals.
- Realize that to reach a particular goal, you may need to abandon other goals.

#### Optimization Strategies

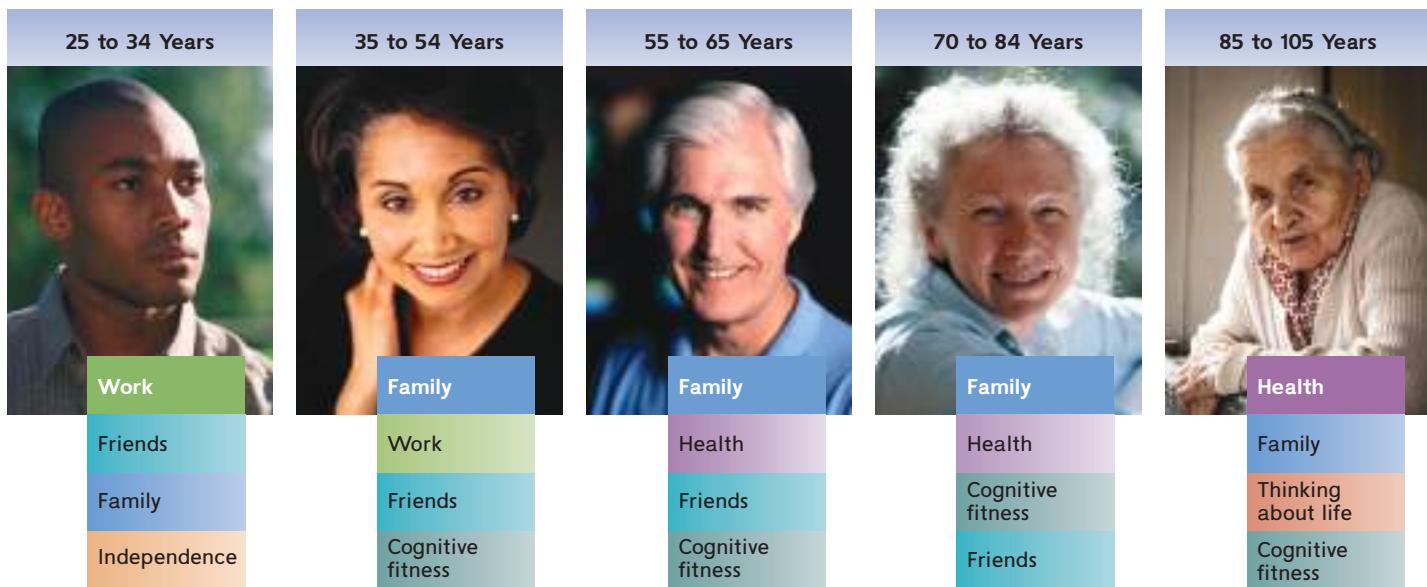

- Keep working on what you have planned until you are successful.
- Persevere and keep trying until you reach your goal.

- When you want to achieve something, you may need to be patient until the right moment arrives.

#### Compensation Strategies

- When things don't go the way they used to, search for other ways to achieve what you want.
- If things don't go well for you, be willing to let others help you.
- When things don't go as well as in the past, keep trying other ways until you can achieve results that are similar to what you accomplished earlier in your life.

*How might you revise these guidelines to include the use of new technologies?*

**FIGURE 3**

#### DEGREE OF PERSONAL LIFE

#### INVESTMENT AT DIFFERENT POINTS IN

**LIFE.** Shown here are the top four domains of personal life investment at different points in life. The highest degree of investment is listed at the top (for example, work was the highest personal investment from 25 to 34 years of age, family from 35 to 84, and health from 85 to 105).

(Left to right) ©Eyewire/Getty Images; ©Photodisc/Getty Images; ©PrestoStock/SuperStock; ©HobbyFinn/Getty Images; ©PointImages/Getty Images

A cross-sectional study by Ursula Staudinger (1996) assessed the personal life investments of 25- to 105-year-olds (see Figure 3). From 25 to 34 years of age, participants said that they personally invested more time in work, friends, family, and independence, in that order. From 35 to 54 and 55 to 65 years of age, family became more important than friends to them in terms of their personal investment. Little changed in the rank ordering of persons 70 to 84 years old, but for participants 85 to 105 years old, health became the most important personal investment. Thinking about life showed up for the first time on the most important list for those who were 85 to 105 years old.

One point to note about the study just described is the demarcation of late adulthood into the subcategories of 70 to 84 and 85 to 105 years of age. This fits with our comments on a number of occasions in this book that researchers increasingly recognize the importance of comparing older adults of different ages rather than studying them as one age group.

## 2 Personality, the Self, and Society

**LG2** Describe links between personality and mortality, and identify changes in the self and society in late adulthood.

Personality

The Self and Society

Older Adults in Society

Do some personality traits change in late adulthood? Is personality linked to mortality in older adults? Do self-perceptions and self-control change in late adulthood? How are older adults perceived and treated by society? We will explore these and other topics in the next few pages.

## PERSONALITY

Recall the Big Five factors of personality. Researchers have found that several of the Big Five factors of personality continue to change in late adulthood (Donnellan, Hill, & Roberts, 2015; Graham & others, 2017; Hampson & Edmonds, 2018; Hill & Roberts, 2016; Jackson & Roberts, 2016; Raketic & others, 2017; Roberts & others, 2017; Strickhouser, Zell, & Krizan, 2017; Terracciano & others, 2017). For example, in one study conscientiousness continued to increase in late adulthood (Roberts, Walton, & Bogg, 2005) and in another study older adults were more conscientious and agreeable than middle-aged and younger adults (Allemand, Zimprich, & Hendriks, 2008).

Might certain personality traits be related to how long older adults live? Researchers have found that some personality traits are associated with the mortality of older adults (Donnellan, Hill, & Roberts, 2015; Hill & Roberts, 2016; Roberts & others, 2017). A longitudinal study of more than 1,200 individuals across seven decades revealed that a higher score on the Big Five personality factor of conscientiousness predicted a lower risk of earlier death from childhood through late adulthood (Martin, Friedman, & Schwartz, 2007). A higher level of conscientiousness has been linked to living a longer life than the other four factors (Donnellan, Hill, & Roberts, 2015; Graham & others, 2017; Jackson & Roberts, 2016; Roberts & Damian, 2018; Wilson & others, 2015). Also, individuals who are extraverted live longer, as do individuals who are low on neuroticism (Graham & others, 2017).

Following are the results of other studies of the influence of the Big Five personality factors in the lives of older adults:

- Older adults with a higher level of conscientiousness experience less cognitive decline as they age (Luchetti & others, 2016).
- A meta-analysis of longitudinal prospective studies indicated that a higher level of conscientiousness reduced the risk of developing Alzheimer disease (Terracciano & others, 2014).
- The transition into late adulthood was characterized by increases in these aspects of conscientiousness: impulse control, reliability, and conventionality (Jackson & others, 2009).
- In older adults, higher levels of neuroticism predicted higher frailty, as did lower levels of openness and agreeableness (Stephan & others, 2017).
- Older adults with a higher level of agreeableness and a lower level of neuroticism were less likely to develop dementia (Terracciano & others, 2017).
- Older adults with higher levels of openness and lower levels of agreeableness engaged in more frequent sexual activity and had lower levels of sexual dysfunction (Allen & Desille, 2017). Also in this study, higher levels of conscientiousness were related to more conservative attitudes about sex and lower levels of sexual dysfunction.
- More severe depression in older adults was associated with higher neuroticism and lower extraversion and conscientiousness (Koorevaar & others, 2013).
- In older adults, higher levels of conscientiousness, openness to experience, agreeableness, and extraversion were linked to positive emotions while neuroticism was associated with negative emotions (Kahlbaugh & Huffman, 2017).
- Elevated neuroticism, lower conscientiousness, and lower openness were related to an increased risk of older adults' developing Alzheimer disease across a period of six years (Duberstein & others, 2011).

Affect (emotion) and outlook on life are also linked to mortality in older adults (Carstensen, 2014, 2015b; Carstensen & others, 2015). Older adults characterized by negative affect don't live as long as those who display more positive affect, and optimistic older adults who have a positive outlook on life live longer than their counterparts who are more pessimistic and have a negative outlook on life (Kolokotroni, Anagnostopoulos & Hantzi, 2018; Reed & Carstensen, 2015).

## THE SELF AND SOCIETY

Our exploration of the self focuses on changes in self-esteem, and self-control. We have described how self-esteem drops in adolescence, especially for girls. How does self-esteem change during the adult years?

### developmental connection

#### Personality

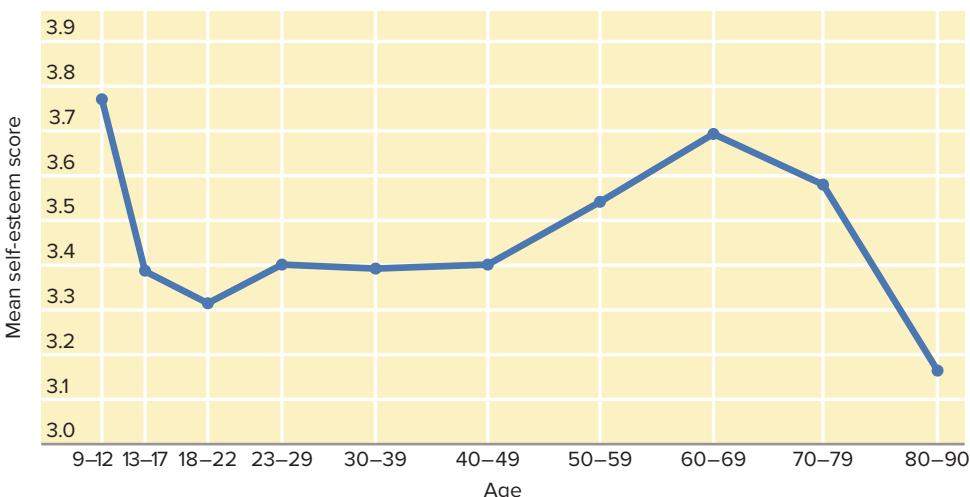

The Big Five factors of personality are openness, conscientiousness, extraversion, agreeableness, and neuroticism. Connect to "Socioemotional Development in Middle Adulthood."

## FIGURE 4

### SELF-ESTEEM ACROSS THE LIFE SPAN.

One cross-sectional study found that self-esteem was high in childhood, dropped in adolescence, increased through early and middle adulthood, then dropped in the seventies and eighties (Robins & others, 2002). More than 300,000 individuals were asked to rate the extent to which they have high self-esteem on a five-point scale, with 5 being "Strongly Agree" and 1 being "Strongly Disagree."

Source: Robins, R. W., Trzesniewski, K. H., Tracey, J. L., Potter, J., & Gosling, S. D. "Age differences in self-esteem from age 9 to 90." *Psychology and Aging*, 17, 2002, 423–434.

**Self-Esteem** In a cross-sectional study of self-esteem, researchers studied a very large, diverse sample of more than 300,000 individuals from 9 to 90 years of age (Robins & others, 2002). About two-thirds of the participants were from the United States. The individuals were asked to respond to the item "I have high self-esteem" on the following five-point scale:

1 Strongly Disagree	2	3	4	5 Strongly Agree
---------------------------	---	---	---	------------------------

Self-esteem increased in the twenties, leveled off in the thirties and forties, rose considerably in the fifties and sixties, and then dropped significantly in the seventies and eighties (see Figure 4). Throughout most of the adult years, the self-esteem of males was higher than the self-esteem of females. However, in the seventies and eighties, the self-esteem of males and females converged.

Why might self-esteem decline in older adults? Explanations include deteriorating physical health and negative societal attitudes toward older adults, although these factors were not examined in the large-scale study just described.

A recent 13-year German longitudinal study found a somewhat more positive portrait of self-esteem in older adults than the study by Robins and others (2002). In the German study of older adults from 70 to 103 years of age, on average self-esteem declined in very old age and when individuals were close to death, but the amount of the decline was small (Wagner & others, 2015). In this study, health problems and disabilities as well as higher levels of loneliness and lower levels of control beliefs were linked to lower self-esteem in late life. In other research on older adults, being widowed, institutionalized, or physically impaired, having a low religious commitment, and experiencing a decline in health are linked to low self-esteem (Giarrusso & Bengtson, 2007). Also, in one study, older adults with more interests had a higher level of self-esteem (Krause & Hayward, 2014). And in a recent study, emotionally unstable individuals' self-esteem declined the most in the second half of life (von Soest & others, 2018). In this study, not having a cohabiting partner, being unemployed, and having a disability each were associated with having a lower level of self-esteem and a steeper decline in self-esteem over a five-year period.

Although older adults may derive self-esteem from earlier successes in some domains, such as work and family, some aspects of their lives require continued support for self-esteem (Smith, 2009). For example, older adults' self-esteem benefits when they are told they are nice and accepted by others. One study revealed that older adults had higher self-esteem when they had a youthful identity and more positive personal experiences (Westerhof, Whitbourne, & Freeman, 2012). And another study also found that older adults with higher self-esteem were more likely to be characterized by successful aging factors (Cha, Seo, & Sok, 2012).

**Self-Control** Although older adults are aware of age-related losses, most still effectively maintain a sense of self-control. Recent research indicates that self-control plays an important

role in older adults' quality of life, with high levels of self-control linked to lower levels of depression and obesity (Bercovitz, Ngnoumen, & Langer, 2019; Levasseur & Couture, 2015; Zanto & Gazzaley, 2017). Also, recent research indicates that having a high sense of control over outcomes in life is linked to better cognitive performance, especially in older adults (Lachman, Agrigoroaei, & Hahn, 2016; Robinson & Lachman, 2017).

Self-control plays an important role in older adults' engagement in health-promoting activities (Bercovitz, Ngnoumen, & Langer, 2019). A study of 65- to 92-year-olds found that self-control was linked to better outcomes for well-being and depression following a six-week program of yoga (Bonura & Tenenbaum, 2014). Another study revealed that self-control was a key factor in older adults' physical activity levels (Franke & others, 2013).

Researchers also have studied how people self-regulate their behavior in specific areas of their lives (Bertrand, Graham, & Lachman, 2013; Bolkan & Hooker, 2012; Drewelies & others, 2018; Lachman, Agrigoroaei, & Hahn, 2016; Robinson & Lachman, 2017). One study examined individuals from 13 to 90 years of age. For the oldest group (60 to 90 years of age), control was lowest in the physical domain; for the youngest group (13 to 18 years of age), it was lowest in the social domain (Bradley & Webb, 1976). Other researchers have found a decline in perceived control of cognitive functioning in older adults (Bertrand & Lachman, 2003).

## OLDER ADULTS IN SOCIETY

Does society negatively stereotype older adults? What are some social policy issues in an aging society?

**Stereotyping Older Adults** Social participation by older adults is often discouraged by **ageism**, which is prejudice against others because of their age, especially prejudice against older adults (Allen, 2016; Avalon, 2018; Avalon & Tesch-Romer, 2017; Gendron, Inker, & Welleford, 2018; Harris & others, 2018; Lytle, Levy, & Meeks, 2018; Mitchell, 2017). Older adults are often perceived as incapable of thinking clearly, learning new things, enjoying sex, contributing to the community, or holding responsible jobs. Many older adults face painful discrimination and might be too polite or timid to attack it. Because of their age, older adults might not be hired for new jobs or might be eased out of old ones; they might be shunned socially; and they might be edged out of their family life. A recent study of 29 European countries examined age discrimination in individuals 15 to 115 years of age (Bratt & others, 2018). In this study, younger individuals showed more age discrimination toward older adults than did older individuals.

The personal consequences of negative stereotyping about aging can be serious (Avalon, 2018; de Leo, 2018; O'Connor & Kelson, 2018; Sao Jose & Amado, 2017; Sargent-Cox, 2017; Sims, 2016; Wilson & Roscigno, 2018). A physician (60 years old himself) told an 80-year-old patient: "Well, of course, you are tired. You just need to slow down. Don't try to do so much. After all, you are very old." Many older adults accept this type of advice even though it is rooted in age stereotyping rather than medical findings.

Ageism is widespread (Allen, 2016; Bratt & others, 2018; Sims, 2016). One study found that men were more likely to negatively stereotype older adults than were women (Rupp, Vodanovich, & Crede, 2005). Research indicates that the most frequent form of ageism is disrespect for older adults, followed by assumptions about ailments or frailty caused by age (Palmore, 2004). However, the increasing number of adults living to an older age has led to active efforts to improve society's image of older adults, obtain better living conditions for older adults, and increase their political clout.

Nonetheless, there are considerable variations in stereotyping of older adults in different countries. A study of European countries found that older adults were perceived as more competent in countries such as Denmark in which they engaged in paid or volunteer work, and perceived as less competent in countries such as Poland in which they were less likely to participate in paid or volunteer work (Bowen & Skirbekk, 2013).

**Policy Issues in an Aging Society** The aging society and older persons' status in this society raise policy issues related to the well-being of older adults (Fernandez-Ballesteros, 2019; George & Ferraro, 2016; Mendoza-Nunez & de la Luz Martinez-Maldonado, 2019; Moon, 2016). These issues include the status of the economy, the provision of health care,

**ageism** Prejudice against others because of their age, especially prejudice against older adults.

supports for families who care for older adults, and generational inequity, each of which we consider in turn.

**Status of the Economy** An important issue involving the economy and aging is concern that the U.S. economy cannot bear the burden of so many older persons, who by reason of their age alone are usually consumers rather than producers. However, not all persons 65 and over are nonworkers, and not all persons 18 to 64 are workers. Thus, it is incorrect to simply describe older adults as consumers and younger adults as producers. However, periodic economic crises place considerable burdens on many older adults, who see their nongovernment retirement funds drop precipitously (Cahill, Giandrea, & Quinn, 2016). Especially worrisome is the low rate of savings among U.S. adults, which has further exacerbated the financial problems of older adults during economic downturns (Topa, Lunceford, & Boyatzis, 2018; Williamson & Beland, 2016). Surveys indicate that Americans' confidence in their ability to retire comfortably reached all-time lows in recent years (Helman, Copeland, & VanDerhei, 2012).

What are some concerns about health care for older adults?

©Fuse/Getty Images

**Health Care** An aging society also brings with it various problems involving health care (Gaugler, 2016; Moon, 2016; Papanicolas, Woskie, & Jha, 2018). Escalating health-care costs are currently the focus of considerable concern (Bail & others, 2018; Hudson, 2016). One factor that contributes to rising health care costs is the increasing proportion of older adults in the population. Older adults have more illnesses, especially chronic diseases, than younger adults do (Adams, 2017; Onder & others, 2018). Older adults see doctors more often, are hospitalized more often, and have longer hospital stays (Quesnel-Vallee, Willson, & Reiter-Campeau, 2016). Approximately one-third of the total health bill of the United States is for the care of adults 65 and over, who comprise only 12 percent of the population. The health care needs of older adults are reflected in Medicare and Medicaid (Keohane & others, 2018; Roohan, 2018; Trivedi, 2016). A special concern is the increasing cost of Alzheimer disease, especially for women, who in a recent analysis bear six times the cost of medical care for Alzheimer disease (Yang & Levey, 2015). Of interest is the fact that until the Affordable Care Act was recently enacted, the United States was the only developed country that did not have a national health-care system. Older adults themselves still pay about one-third of their total health-care costs. Thus, older adults as well as younger adults are adversely affected by rising medical costs (Adams, 2017; Green & Saltz, 2018).

A special concern is that while many of the health problems of older adults are chronic rather than acute, the medical system is still based on a "cure" rather than a "care" model. Chronic illness is long-term, often lifelong, and requires long-term, if not lifelong, management (Kaltsatou, 2017; MacNeil Vroomen & others, 2018; Mihailoff & others, 2018). Chronic illness often follows a pattern of an acute period that may require hospitalization, followed by a longer period of remission, and then repetitions of this pattern. The patient's home, rather than the hospital, often becomes the location for managing the patient's chronic illness. In a home-based system, a new type of cooperative relationship between doctors, nurses, patients, family members, and other service providers needs to be developed (Kamp, Wellman, & Russell, 2010). Health-care personnel need to be trained and be available to provide services in patients' homes (Irish, 2011).

**Eldercare** **Eldercare** is the physical and emotional caretaking of older members of the family, whether that care involves day-to-day physical assistance or responsibility for arranging and overseeing such care. An important issue involving eldercare is how it can best be provided (Andersson, Hanberger, & Nygren, 2018; Karstad & others, 2018; Sin & others, 2017). With so many women in the labor market, who will replace them as caregivers? An added problem is that many caregivers are in their sixties, and many of them are ill themselves. They may find it especially stressful to be responsible for the care of relatives who are in their eighties or nineties.

**Generational Inequity** Yet another policy issue involving aging is **generational inequity**, the view that our aging society is being unfair to its younger members because older adults pile up advantages by receiving an inequitably large allocation of resources (Jones & Roy, 2017; Kershaw, 2018). Some authors have argued that generational inequity produces intergenerational conflict and divisiveness in the society at large (Longman, 1987). The generational equity issue raises questions about whether the young should be required to pay for the old (Hudson, 2016; Jones & Roy, 2017). This concern has especially increased with the enactment of the

**eldercare** Physical and emotional caretaking for older members of the family, whether by giving day-to-day physical assistance or by being responsible for overseeing such care.

**generational inequity** The view that our aging society is being unfair to its younger members because older adults pile up advantages by receiving inequitably large allocations of resources.

government's Affordable Care Act in which healthy younger adults, who use the health-care system far less than older adults, nonetheless are required to sign up for the health-care program or pay a penalty (Hero, Zaslavsky, & Blendon, 2017).

**Income** Economic security is clearly one of the most important aspects of older adults' well-being (Antonucci & others, 2016). Many older adults are understandably concerned about the adequacy of their income (Topa, Lunceford, & Boyatzis, 2018). Of special concern are older adults who are poor (George & Ferraro, 2016). Researchers have found that poverty in late adulthood is linked to an increase in physical and mental health problems (George & Ferraro, 2016). Poverty also is linked to lower levels of physical and cognitive fitness in older adults (Johnson & others, 2011). A recent study found that processing speed was slower in older adults living in poverty (Zhang & others, 2015). Research studies reveal that low SES is linked to increased risk of earlier death in older adults (Domenech-Abella & others, 2018; Krueger & Chang, 2008).

Census data suggest that the overall number of older people living in poverty has declined since the 1960s, but in 2014, 10 percent of older adults in the United States still were living in poverty (U.S. Census Bureau, 2016a). In 2014, U.S. women 65 years and older (12 percent) were much more likely to live in poverty than their male counterparts were (7 percent) (U.S. Census Bureau, 2016a). There is a special concern about poverty among older women and considerable discussion about the role of Social Security in providing a broad economic safety net for them (Cahill, Giandrea, & Quinn, 2016; Couch & others, 2017; Moon, 2016).

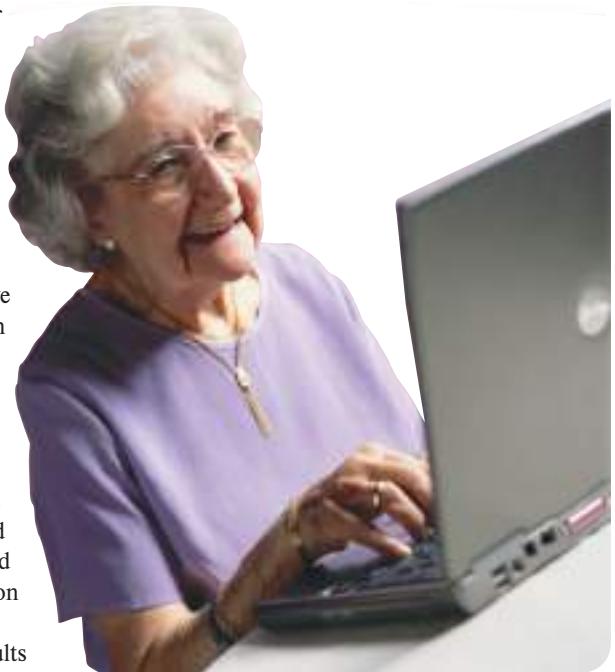

Poverty rates among older adults who belong to ethnic minorities are much higher than the rate for non-Latino Whites. In 2013, 20 percent of Latino White older adults and 18 percent of African American older adults lived in poverty, compared with 7 percent of non-Latino Whites (Cubanski, Casillas, & Damice, 2015). Combining gender and ethnicity, 41 percent of older Latinas and 31 percent of African American women lived in poverty in 2010 (U.S. Census Bureau, 2011). Also, the oldest-old are the age subgroup of older adults most likely to be living in poverty (Cubanski, Casillas, & Damice, 2015).

However, it is not just individuals in low-income, poverty conditions who harbor fears of not having enough money in their older adult years. A study of older adults whose savings had been depleted by the 2008 U.S. recession found that the loss of wealth had increased their feelings of depression and use of antidepressant drugs (McInerney, Mellor, & Nicholas, 2013).

**Living Arrangements** One stereotype of older adults is that they are often residents in institutions—hospitals, mental hospitals, nursing homes, and so on. However, nearly 95 percent of older adults live in the community. Almost two-thirds of older adults live with family members—their spouse, a child, or a sibling, for example—and almost one-third live alone. The older people become, the greater their likelihood of living alone. Half of older women 75 years and older live alone. The majority of older adults living alone are widowed, encompassing three times as many women as men (U.S. Census Bureau, 2016b). Older adults who live alone often report being more lonely than their counterparts who live with someone (Kirkevold & others, 2013). However, as with younger adults, living alone as an older adult does not necessarily mean being lonely. Older adults who can sustain themselves while living alone often have good health and few disabilities, and they may have regular social exchanges with relatives, friends, and neighbors.

**Technology** The Internet plays an increasingly important role in providing access to information and communication for older adults as well as younger adults and youth (Charness & Boot, 2016; Gavett & others, 2017; Gillain & others, 2019; Ware & others, 2017). A longitudinal study revealed that Internet use by older adults reduced their likelihood of being depressed by one-third (Cotten & others, 2014). And in a recent study of older adults, having an iPad strengthened their family ties and brought a greater sense of overall connection to society (Delelo & McWhorter, 2017).

How well are older adults keeping up with changes in technology? Older adults are less likely to have a computer in their home and less likely to use the Internet than younger adults are, but older adults are the fastest-growing segment of Internet users. In 2016, 67 percent of U.S. adults 65 years of age and over used the Internet, up from 59 percent

Are older adults keeping up with changes in technology?  
©Peter Dazeley/Photographer's Choice/Getty Images

in 2013 and 14 percent in 2000 (Anderson, 2017). In the general U.S. population, 90 percent are Internet users. Younger seniors use the Internet more than older seniors do (82 percent of 65- to 69-year-olds, compared with 44 percent of adults 80 years of age and older).

Increasing numbers of older adults use e-mail and smart phones to communicate, especially with friends and relatives (Gillain & others, 2019). In 2016, approximately 40 percent of U.S. adults 65 years of age and older were smartphone users, up 24 percent from 2013 (Anderson, 2017). In this survey, 59 percent of 65- to 69-year-olds but only 17 percent of adults age 80 and older used smartphones. For both Internet and smartphone use, lower-SES older adults use these communication tools much less than middle- and upper-SES older adults.

Older adults also are using social media more than in the past. In 2016, 34 percent of U.S. adults 65 and over reported using social networking sites like Facebook and Twitter, 7 percent higher than in 2013 (Anderson, 2017).

A recent study in Hong Kong found that adults 75 and older who used smartphones and the Internet to connect with family, friends, and neighbors had a higher level of psychological well-being than their counterparts who did not use this information and communicative technology (Fang & others, 2018). As with children and younger adults, cautions about verifying the accuracy of information—especially on topics involving health care—on the Internet should always be kept in mind (Miller & Bell, 2012).

Although computers and the Internet are now playing more important roles in people's lives at all ages today, people continue to watch extensive amounts of television, especially in late adulthood. In a recent 2016 Nielsen survey, adults age 65 and older watched television an average of 51 hours, 32 minutes per week (Recode, 2016). That 51+ hours per week is far more than any other adult age group—18 to 24 years (16 hrs, 18 min), 25 to 34 years (23 hrs, 26 min), 35 to 49 years (32 hrs, 7 min), and 50 to 64 years (44 hrs, 6 min). The staggering number of hours older adults spend watching television each week raises concerns about how such lengthy sedentary behavior can reduce the amount of time spent engaging in adequate physical exercise and social activities, which are linked to healthy physical and socioemotional development.

## 3 Families and Social Relationships

**LG3**

Characterize the families and social relationships of aging adults.

Are the close relationships of older adults different from those of younger adults? What are the lifestyles of older adults like? What characterizes the relationships of older adult parents and their adult children? Is the role of great-grandparents different from the role of grandparents? What do friendships and social networks contribute to the lives of older adults? What

types of social support do older adults need and want? How might older adults' altruism and volunteerism contribute to positive outcomes?

## LIFESTYLE DIVERSITY

The lifestyles of older adults are changing. Formerly, the later years of life were likely to consist of marriage for men and widowhood for women. With demographic shifts toward marital dissolution characterized by divorce, one-third of adults can now expect to marry, divorce, and remarry during their lifetime. Let's now explore some of the diverse lifestyles of older adults, beginning with those who are married or partnered.

**Married Older Adults** In 2016, 57.8 percent of U.S. adults over 65 years of age were married (U.S. Census Bureau, 2017). Older men were far more likely to be married than older women. In 2016, 24 percent of U.S. adults over 65 years of age were widowed (U.S. Census Bureau, 2017). There were more than four times as many widows as widowers.

The time from retirement until death is sometimes referred to as the "final stage in the marriage process." The portrait of marriage in the lives of older adults is a positive one for many couples (Blieszner, 2018; Piazza & Charles, 2012). Individuals who are in a marriage or a partnership in late adulthood usually are happier, are less distressed, and live longer than those who are single (Peek, 2009). The following studies support the view that positive marital relationships are linked to a number of positive outcomes for older adults:

- Marital satisfaction helped to insulate older adults' happiness from the effects of daily fluctuations in perceived health (Waldinger & Schulz, 2010).
- More frequent negative (but not positive) marital experiences resulted in a slower increase of cognitive limitations over time (Xu, Thomas, & Umberson, 2016).
- Compared with other sources of social support, spousal support was more strongly linked to an important biomarker of cellular aging, telomere length (Barger & Cribbet, 2016).
- A longitudinal study of adults 75 years of age and older revealed that individuals who were married were less likely to die during a seven-year time span (Rasulo, Christensen, & Tomassini, 2005).
- Marital satisfaction in older adults was linked to whether an individual was depressed or not (Walker & others, 2013).
- For both married and cohabiting couples, negative relationship quality predicted higher blood pressure when both members of the couple reported having negative relationship quality (Birditt & others, 2016).

Retirement alters a couple's lifestyle, requiring adaptation (Suttor, Gilligan, & Pillemer, 2016). The greatest changes occur in the traditional family structure in which the husband works and the wife is a homemaker. The husband may not know what to do with his time, and his wife may feel uneasy having him around the house so much of the day. In traditional families, both partners may need to move toward more egalitarian roles. The husband must adjust from being the provider outside of the home to being a helper around the house; the wife must change from being the only homemaker to being a partner who shares and delegates household duties. Marital happiness of older adults is also affected by each partner's ability to deal with personal challenges, including aging, illness, and the prospect of widowhood.

In late adulthood, married individuals are more likely to find themselves having to care for a sick partner with a limiting health condition (Anderson, Keating, & Wilson, 2017; Monin & others, 2018; Suttor, Gilligan, & Pillemer, 2016). The stress of caring for a spouse who has a chronic disease can place demands on intimacy (Polenick & DePasquale, 2018).

How might marriage influence outcomes in extremely old adults? A recent study explored centenarians' marital history and living arrangements (Poulain & Herm, 2016). In this study, between the ages of 60 and 100, male centenarians lived twice as long with their wives as female centenarians did with their husbands. Male centenarians were more likely to have younger wives and female centenarians were more likely to have older husbands than non-centenarians.

How might marriage affect the health and well-being of LGBT older adults? In a recent study of LGBT individuals 50 years and older, 24 percent were legally married, 26 percent

I am the family face;  
Flesh perishes,  
I live on,  
Projecting trait and trace  
Through time to times anon,  
And leaping from place to  
place  
Over oblivion.

unmarried and partnered, and 50 percent single (Goldsen & others, 2017). In this study, those who were legally married reported having a better quality of life and more economic and social resources than their unmarried and partnered counterparts. And those who were single reported having poorer health and fewer resources than those who were legally married or unmarried and partnered.

**Divorced and Remarried Older Adults** An increasing number of older adults are divorced (Lin & others, 2018; Suitor, Gilligan, & Pillemer, 2016). In a recent comparison, in 1980, 3 percent of women 65 years and older were divorced, but that rate had increased to 13 percent in 2015; for men, in 1980 4 percent of those 65 and older were divorced, but that rate had increased to 11 percent in 2015 (U.S. Census Bureau, 2016a). Many of these individuals were divorced or separated before entering late adulthood. The majority of divorced older adults are women, due to their greater longevity. Men are more likely than women to remarry, thus removing themselves from the pool of divorced older adults (Peek, 2009). Divorce is far less common among older adults than younger adults, likely reflecting cohort effects rather than age effects since divorce was somewhat rare when current cohorts of older adults were young (Peek, 2009). In a recent study, many of the same factors traditionally associated with divorce in younger adults were also likely to occur in older adults (Lin & others, 2018). Older adults who had been married for many years, who had better marital quality, who owned a home, and who were wealthy were less likely than other older couples to get divorced. Another recent study found that partnered older adults were more likely to receive Social Security and enjoy relatively high Social Security benefits, and less likely to live in poverty (Lin, Brown, & Hammersmith, 2017).

There are social, financial, and physical consequences of divorce for older adults (Suitor, Gilligan, & Pillemer, 2016). Divorce can weaken kinship ties when it occurs in later life, especially in the case of older men. Divorced older women are less likely to have adequate financial resources than married older women, and older adults who are divorced have more health problems than those who are not (Bennett, 2006).

Rising divorce rates, increased longevity, and better health have led to an increase in remarriage among older adults (Ganong, Coleman, & Sanner, 2018; Koren & others, 2016; Papernow, 2018). What happens when an older adult who is divorced or widowed wants to remarry or does remarry? Some older adults perceive negative social pressure about their decision to remarry. These negative sanctions range from raised eyebrows to rejection by adult children (Ganong & Coleman, 2018). However, the majority of adult children support the decision of their older adult parents to remarry. A research analysis revealed that divorce rates were 2.5 times higher for middle-aged and older adults who had remarried than for those in first marriages (Brown & Lin, 2012).

Researchers have found that remarried parents and stepparents provide less support to adult stepchildren than parents in first marriages provide to their adult children (Ganong, Coleman, & Sanner, 2018). One study revealed relatively weak ties between older adults and their stepchildren (Noel-Miller, 2013). In this study, older stepparents' social contact with their stepchildren was mainly linked to the stepparent continuing to be married to the stepchildren's biological parent. When divorce occurred in an older adult stepfamily, the divorced stepparent's frequency of contact with stepchildren dropped abruptly.

**Cohabiting Older Adults** An increasing number of older adults cohabit (Wright & Brown, 2017). In 1960, hardly any older adults cohabited (Chevan, 1996). Since 2007, the number of cohabiting adults 50 years and older has risen 75 percent (Stepler, 2017). In 2016, 4 million adults 50 years and older were cohabiting, up from 2.3 million in 2007. It is expected that the number of cohabiting older adults will increase further as the large cohort of baby boomers continues to move through late adulthood, bringing their historically more nontraditional attitudes regarding love, sex, and relationships with them. In many cases, cohabiting is more for companionship than for love. In other cases, such as when one partner faces the potential for expensive care, a couple may decide to maintain their assets separately and thus not marry. One study found that older adults who cohabited had a more positive, stable relationship than younger adults who cohabited, although older adults were less likely to have plans to marry their partner (King & Scott, 2005).

Does cohabiting affect an individual's health and psychological well-being? A study of more than 8,000 51- to 61-year-old adults revealed that the health of couples who cohabited

### developmental connection

#### Widows

Women 65 years and older are far more likely to be widowed than to be divorced. Connect to "Death, Dying, and Grieving."

did not differ from the health of married couples (Waite, 2005). However, another study of individuals 50 years of age and older found that those who cohabited were more depressed than their married counterparts (Brown, Bulanda, & Lee, 2005). And in a recent national study of older adults, among men, cohabiters' psychological well-being (lower levels of depression, stress, and loneliness) fared similarly to married men, better than daters and the unpartnered (Wright & Brown, 2017). In contrast, there were few differences in the psychological well-being of women who were married, cohabiting, or single.

## ATTACHMENT

There has been far less research on attachment in aging adults than on attachment in children, adolescents, and young adults (Freitas & Rahioul, 2017; Homan, 2018). A research review on attachment in older adults reached the following conclusions (Van Assche & others, 2013):

- Older adults have fewer attachment relationships than younger adults do (Cicirelli, 2010).
- In late adulthood, attachment security is associated with greater psychological and physical well-being than attachment anxiety (Bodner & Cohen-Fridel, 2010).
- Insecure attachment is linked to more perceived negative caregiver burden in caring for patients with Alzheimer disease (Karantzas, Evans, & Foddy, 2010).
- Also, in a longitudinal study of individuals from 13 to 72 years of age, attachment anxiety declined in middle-aged and older adults (Chopik, Edelstein, & Grimm, 2018). Attachment avoidance decreased in a linear fashion across the life span. Being in a relationship was linked to lower rates of attachment anxiety and attachment avoidance across adulthood. And men were higher than women in attachment avoidance throughout the life span.

## OLDER ADULT PARENTS AND THEIR ADULT CHILDREN

Parent-child relationships in later life differ from those earlier in the life span (Antonucci & others, 2016; Birditt & others, 2018; Huo & others, 2018a, b; Lowenstein, Katz, & Tur-Sanai, 2018). They are influenced by a lengthy joint history and extensive shared experiences and memories.

Approximately 80 percent of older adults have living children, many of whom are middle-aged. About 10 percent of older adults have children who are 65 or older. Adult children are an important part of the aging parent's social network. Researchers have found that older adults with children have more contacts with relatives than those without children (Johnson & Troll, 1992).

Increasingly, diversity characterizes the lifestyles of older adult parents and their adult children (Lowenstein, Katz, & Tur-Sanai, 2018). Divorce, remarriage, cohabitation, and non-marital childbearing are more common in the history of older adults today than in the past (Papernow, 2018; Wright & Brown, 2017).

Gender plays an important role in relationships involving older adult parents and their children (Antonucci & others, 2016). Adult daughters are more likely than adult sons to be involved in the lives of their aging parents. For example, adult daughters are three times more likely than are adult sons to give parents assistance with daily living activities (Dwyer & Coward, 1991).

Middle-aged adults are more likely to provide support if their parents have a disability (Huo & others, 2018b). A valuable service that adult children can perform is to coordinate and monitor services for an aging parent who becomes disabled (Jones & others, 2011). Even less severely impaired older adults may need help with shopping, housework, transportation, home maintenance, and bill paying.

Some researchers have found that relationships between aging parents and their children are usually characterized by ambivalence (Birditt & others, 2018; Sechrist & Fingerman, 2018). Perceptions include love, reciprocal help, and shared values on the positive side and isolation, family conflicts and problems, abuse, neglect, and caregiver stress on the negative side. A study of adult children's relationships with their older adult parents revealed that ambivalence was likely to be present when relationships involved in-laws, those in poor health, and adult children with poor parental relationships in early life (Wilson, Shuey, & Elder, 2003). Another study,

At the beginning of the twentieth century, the three-generation family was common, but now the four-generation family is common as well. Thus, an increasing number of grandparents are also great-grandparents. The four-generation family shown here is the Jordans—author John Santrock's mother-in-law, daughter, granddaughter, and wife.

### developmental connection

#### Family and Peers

It takes time to develop intimate friendships, so friendships that have endured over the adult years are often deeper than those that have just been formed in middle adulthood. Connect to “Socioemotional Development in Middle Adulthood.”

though, revealed that affection and support, reflecting solidarity, were more prevalent than ambivalence in intergenerational relationships (Hogerbrugge & Komter, 2012). And researchers have found that middle-aged adults feel more positive about providing support for their children than for their aging parents (Birditt & others, 2018).

## GREAT-GRANDPARENTING

Because of increased longevity, more grandparents today than in the past are also great-grandparents. At the turn of the twentieth century, the three-generation family was common, but now the four-generation family is common. One contribution of great-grandparents is to transmit family history by telling their children, grandchildren, and great-grandchildren where the family came from, what their members achieved, what they endured, and how their lives changed over the years (Harris, 2002).

There has been little research on great-grandparenting. One study examined the relationship between young adults and their grandparents and great-grandparents (Roberto & Skoglund, 1996). The young adults interacted with, and participated in more activities with, their grandparents than with their great-grandparents. They also perceived their grandparents as having a more defined role and being more influential in their lives than their great-grandparents were.

## FRIENDSHIP

In early adulthood, friendship networks expand as new social connections are made away from home. In late adulthood, new friendships are less likely to be forged, although some older adults do seek out new friendships, especially following the death of a spouse (Adams, Hahmann, & Blieszner, 2017; Blieszner & Ogletree, 2017, 2018).

A recent study found that compared with younger adults, older adults reported fewer problems with friends, fewer negative friendship qualities, less frequent contact with friends, and more positive friendship qualities with a specific friend (Schlosnagle & Strough, 2017). In another study, adults who had close ties with friends were less likely to die across a seven-year age span (Rasulo, Christensen, & Tomassini, 2005). These findings were stronger for women than for men.

Aging expert Laura Carstensen and her colleagues (1998, 2009; Charles & Carstensen, 2010; Sims, Hogan, & Carstensen, 2015) concluded that people choose close friends over new friends as they grow older. And as long as they have several close people in their network, they seem content, says Carstensen. Supporting Carstensen's view, researchers found that in comparison with younger adults, older adults said they tended to experience less intense positive emotions with new friends and equal levels of positive emotions with established friends (Charles & Piazza, 2007) (see Figure 5).

## SOCIAL SUPPORT AND SOCIAL INTEGRATION

Social support and social integration play important roles in the physical and mental health of older adults (Antonucci & Webster, 2019; Huang & others, 2017; Shankar & others, 2017; Smith & others, 2018).

**Social Support** In the **convoy model of social relations**, individuals go through life embedded in a personal network of individuals to whom they give and from whom they receive social support (Antonucci & others, 2016; Antonucci & Webster, 2019). For older adults, social support is related to their physical health, mental health, and life satisfaction (Howard & others, 2017; Tkatch & others, 2017). In a recent study, a higher level of social support was associated with older adults' increased life satisfaction (Dumitache, Rubio, & Rubio-Herrera, 2017). It also is linked with a reduction in symptoms of disease, with the ability to meet one's own health-care needs, and reduced mortality (Rook & others, 2007; Smith & others, 2018). A higher level of social support also is related to a lower probability of an older adult being institutionalized and depressed (Herd, Robert, & House, 2011). Further, one study revealed that older adults who experienced a higher level of social

**convoy model of social relations** Model in which individuals go through life embedded in a personal network of individuals to whom they give and from whom they receive support.

support showed later cognitive decline than their counterparts with a lower level of social support (Dickinson & others, 2011). And a recent study found that emotional and finance-related social support were linked to higher levels of physical activity in older adults (Loprinzi & Joyner, 2016).

Social support for older adults can be provided by different adults (Antonucci & others, 2016; Antonucci & Webster, 2019). Older adults who are married are less likely to need formal social supports, such as home nursing care, adult day care, and home-delivered meals, than are nonmarried older adults. Families play important roles in social support for older adults, but friends also can provide invaluable resources for social support (Blieszner & Ogletree, 2017, 2018; Blieszner & Roberto, 2012). Recent analyses, though, indicate that 80 percent of supportive care for older adults with some form of limitation is provided by family members or other informal caregivers, which places an enormous burden on the caregiver (Antonucci & others, 2016; Antonucci & Webster, 2019; Sherman, Webster, & Antonucci, 2016). Also, social support for older adults may vary across cultures. For example, in the United States, the focal support person for an older adult is most likely to be a daughter, whereas in Japan it is most likely to be a daughter-in-law.

**Social Integration** Social integration also plays an important role in the lives of many older adults (Antonucci & Webster, 2019; Dong & Chang, 2017; Hawley & Kocherginsky, 2018). A recent study found that older adults with higher levels of social integration were less depressed (Ivan Santini & others, 2015).

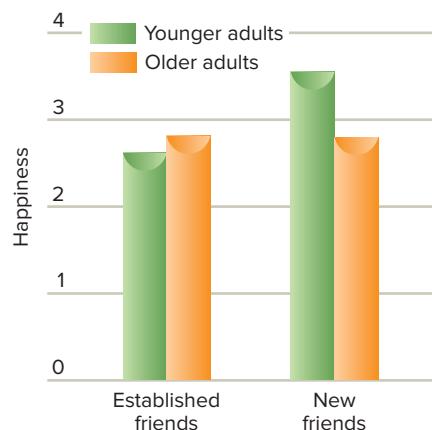

Remember from our earlier discussion of socioemotional selectivity theory that many older adults choose to have fewer peripheral social contacts and more emotionally positive contacts with friends and family (Carstensen & others, 2011, 2015; Carstensen, 2015a, b, 2016). Thus, a decrease in the overall social activity of many older adults may reflect their greater interest in spending more time in the small circle of friends and family members where they are less likely to have negative emotional experiences. Researchers have found that older adults tend to report being less lonely than younger adults and less lonely than would be expected based on their circumstances (Schnittker, 2007). Their reports of feeling less lonely than younger adults likely reflect their more selective social networks and greater acceptance of solitude in their lives (Antonucci & others, 2016; Antonucci & Webster, 2019). In a recent study, 18 percent of older adults stated they were often or frequently lonely (Due, Sandholdt, & Waldorff, 2018). In this study, the most important predictors of feeling lonely were anxiety and depressive symptoms, living alone, and low social participation. Also, in a national longitudinal study, loneliness was linked with earlier death (Luo & others, 2012).

## ALTRUISM AND VOLUNTEERING

Are older adults more altruistic than younger adults? In a series of studies, older adults were more likely to behave in altruistic ways and to value contributions to the public good than younger adults were (Freund & Blanchard-Fields, 2014). For example, in two of the studies, older adults were more likely than younger adults to donate money for a good cause.

A common perception is that older adults need to be given help rather than give help themselves. A national survey found that 24.1 percent of U.S. adults 65 years and older engaged in volunteering in 2013 (U.S. Bureau of Labor Statistics, 2013). In this survey, the highest percentage of volunteering occurred between 35 and 44 years of age (30.6 percent). However, older adults are more likely than any other age group to volunteer more than 100 hours annually (Burr, 2009). Almost 50 percent of the volunteering efforts of older adults are for services provided by religious organizations (Burr, 2009).

Might volunteering improve the well-being and life-satisfaction of older adults? Volunteering is associated with a number of positive outcomes for aging adults (Carr, 2018; Guiney & Machado, 2018). Recent studies have found that when aging adults volunteer, they have better health (Burr & others, 2018; Carr, Kail, & Rowe, 2018), have better cognitive functioning (Proulx, Curl, & Ermer, 2018), and are less lonely (Carr & others, 2018). Among the reasons for the positive outcomes of volunteering are its provision of constructive activities and productive roles, social integration, and enhanced meaningfulness (Tan & others, 2007).

## developmental connection

### Community and Culture

Service learning is linked with numerous positive outcomes in youth. Connect to “Physical and Cognitive Development in Adolescence.”

Might providing help to others even be linked to longevity in late adulthood? In a recent study, of four indices (volunteering, informally helping others through a modest time commitment, attendance at religious services, and going to social group meetings), the strongest predictor of longevity and lower risk for cardiovascular disease was volunteering (Han, S. H., & others, 2017). Also, a recent study revealed that older adults who volunteered regularly had a lower risk of cognitive impairment (Infurna, Okun, & Grimm, 2016). And in a research meta-analysis, older adults who engaged in organizational volunteering had a lower mortality risk than those who did not (Okun, Yeung, & Brown, 2013).

## Review Connect Reflect

**LG3** Characterize the families and social relationships of aging adults.

### Review

- How would you profile the diversity of adult lifestyles?
- How does attachment change in older adults?
- What characterizes the relationships of older adult parents and their adult children?
- Is the role of great-grandparents different from the role of grandparents?
- What are friendships of older adults like?
- What roles do social support and social integration play in late adulthood?
- How are altruism and volunteerism linked to positive outcomes in older adults?

### Connect

- In this section, you read that a low level of social integration is linked with coronary heart disease in older adults. What have you already learned about heart disease and stress in middle adulthood?

### Reflect Your Own Personal Journey of Life

- If you are an emerging or young adult, what is the nature of the relationship of your parents with their parents and grandparents (if they are alive)? If you are a middle-aged adult, how would you characterize your relationship with your parents (if they are still alive)?

## 4 Ethnicity, Gender, and Culture

**LG4**

Summarize how ethnicity, gender, and culture are linked with aging.

How is ethnicity linked with aging? Do gender roles change in late adulthood? What are the social aspects of aging in different cultures?

### ETHNICITY

Of special concern are ethnic minority older adults, especially African Americans and Latinos, who are overrepresented in poverty statistics (Antonucci & others, 2016). Consider Harry, a 72-year-old African American who lives in a rundown hotel in Los Angeles. He suffers from arthritis and uses a walker. He has not been able to work for years, and government payments are barely enough to meet his needs.

Comparative information about African Americans, Latinos, and Whites indicates a possible double jeopardy for elderly ethnic minority individuals. They face problems related to both ageism and racism (Allen, 2016; McCluney & others, 2018). Both the wealth and the health of ethnic minority older adults decrease more rapidly than for elderly non-Latino Whites (Angel, Mudrazija, & Benson, 2016). Older ethnic minority individuals are more likely to become ill but less likely to receive treatment (Angel, Mudrazija, & Benson, 2016; Nguyen & others, 2018). They also are more likely to have a history of less education, higher levels of unemployment, worse housing conditions, and shorter life expectancies than their non-Latino

## connecting with careers

### Norma Thomas, Social Work Professor and Administrator

Dr. Norma Thomas has worked for more than three decades in the field of aging. She obtained her undergraduate degree in social work from Pennsylvania State University and her doctoral degree in social work from the University of Pennsylvania. Thomas' activities are varied. Earlier in her career, as a social work practitioner, she provided services to older adults of color in an effort to improve their lives. She currently is a professor and academic administrator at Widener University in Chester, Pennsylvania, a fellow of the Institute of Aging at the University of

Pennsylvania, and the chief executive officer and cofounder of the Center on Ethnic and Minority Aging (CEMA). CEMA was formed to provide research, consultation, training, and services to benefit aging individuals of color, their families, and their communities. Thomas has created numerous community service events that benefit older adults of color, especially African Americans and Latinos. She has also been a consultant to various national, regional, and state agencies in her effort to improve the lives of aging adults of color.

*For more information about what professors and social workers do, see the Careers in Life-Span Development appendix.*

Norma Thomas.  
Courtesy of Dr. Norma Thomas

White counterparts (Treas & Gubernskaya, 2016). Also, too many ethnic minority workers never enjoy the Social Security and Medicare benefits to which their earnings contribute, because they die before reaching the age of eligibility for benefits. And non-Latino White men and women with 16 years or more of schooling have been found to have a life expectancy 14 years higher than African Americans with fewer than 12 years of education (Antonucci & others, 2016; Olshansky & others, 2012).

Despite the stress and discrimination older ethnic minority individuals face, many of these older adults have developed coping mechanisms that allow them to survive in the dominant non-Latino White world. Extension of family networks helps older minority-group individuals cope with the bare essentials of living and gives them a sense of being loved (Karasik & Hamon, 2007). Churches in African American and Latino communities provide avenues for meaningful social participation, feelings of power, and a sense of internal satisfaction (Hill & others, 2006). And residential concentrations of ethnic minority groups give their older members a sense of belonging. Thus, it always is important to consider individual variations in the lives of aging minorities.

Further, a recent study found that the life satisfaction of Latino older adults was higher than for African American and non-Latino White older adults (Zhang, Braun, & Wu, 2017). And in another recent study, older adult immigrants had higher levels of life satisfaction than native-born older adult U.S. residents did (Calvo, Carr, & Matz-Costa, 2017). In this study, Latino immigrants had the highest life satisfaction of all the groups studied. These findings have recently been called a "happiness paradox" because older Latino immigrants have been found to have greater life satisfaction than native-born Latinos and non-Latino Whites in the United States, despite experiencing the greatest financial disadvantages and limitations (Calvo, Carr, & Matz-Costa, 2017, 2018).

To read about one individual who is providing help for aging minorities, see *Connecting with Careers*.

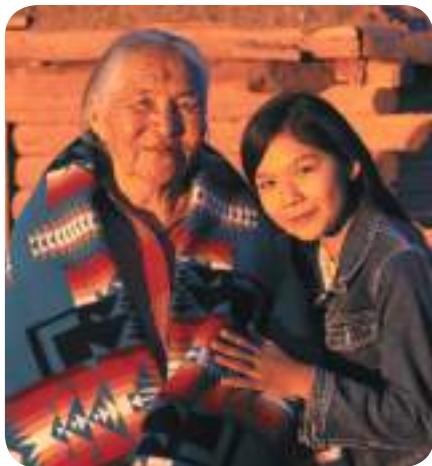

## GENDER

Do our gender roles change when we become older adults? Some developmentalists conclude that femininity decreases in women and that masculinity decreases in men when they reach late adulthood (Gutmann, 1975). The evidence suggests that older men do become more

A special concern is the stress faced by older African American women, many of whom view religion as a source of strength to help them cope. *What are some other characteristics of being female, a member of an ethnic minority, and old?*

©Matt Gray/Getty Images

Cultures vary in the prestige they give to older adults. In the Navajo culture, older adults are especially treated with respect because of their wisdom and extensive life experiences. *What are some other factors that are linked with respect for older adults in a culture?*

©Alison Wright/Corbis/Getty Images

feminine—nurturant, sensitive, and so on—but it appears that older women do not necessarily become more masculine—assertive, dominant, and so on (Turner, 1982). In a more recent cross-sectional study of individuals from 12 to 80 years and older, men in their seventies were more likely than adolescents and younger men to endorse androgynous traits (Strough & others, 2007). Also in this study, women in their eighties and older were less likely than younger and middle-aged women to endorse masculine and androgynous traits. And in an even more recent study, among older adult men, those who were married were more likely to endorse stereotypically masculine traits but also to have higher androgyny scores than unmarried older men (Lemaster, Delany, & Strough, 2017). The studies of age differences just discussed here were cross-sectional in nature and may reflect cohort effects. Keep in mind that cohort effects are especially important to consider in areas such as gender roles. As sociohistorical changes take place and are assessed more frequently in life-span investigations, what were once perceived to be age effects may turn out to be cohort effects (George & Ferraro, 2016).

A possible double jeopardy also faces many women—the burden of both ageism and sexism (Angel, Mudrazija, & Benson, 2016). Not only is it important to be concerned about older women's double jeopardy of ageism and sexism, but special attention also needs to be devoted to female ethnic minority older adults (Jackson, Govia, & Sellers, 2011). They face what could be described as triple jeopardy—ageism, sexism, and racism (Hinze, Lin, & Andersson, 2012). Older women in ethnic minority groups have faced considerable stress in their lives. In dealing with this stress, they have shown remarkable adaptability, resilience, responsibility, and coping skills.

## CULTURE

What promotes a good old age in most cultures? One analysis indicated that three factors are important in living the “good life” as an older adult: health, security, and kinship/support (Fry, 2007).

Another important question is this: What factors are associated with whether older adults are accorded a position of high status in a culture? In one view, seven factors are most likely to predict high status for older adults in a culture (Sangree, 1989):

- Older persons have valuable knowledge.
- Older persons control key family/community resources.
- Older persons are permitted to engage in useful and valued functions as long as possible.
- There is role continuity throughout the life span.
- Age-related role changes involve greater responsibility, authority, and advisory capacity.
- The extended family is a common family arrangement in the culture, and the older person is integrated into the extended family.
- In general, respect for older adults is greater in collectivistic cultures (such as China and Japan) than in individualistic cultures (such as the United States). However, some researchers are finding that this collectivistic/individualistic difference in respect for older adults is not as strong as it used to be, and that in some cases older adults in individualistic cultures receive considerable respect (Antonucci, Vandewater, & Lansford, 2000).

## Review Connect Reflect

**LG4** Summarize how ethnicity, gender, and culture are linked with aging.

### Review

- How does ethnicity modify the experience of aging?
- Do gender roles change in late adulthood? Explain.
- How is aging experienced in different cultures?

### Connect

- In this section, you read that ethnic minorities face additional challenges

in aging. What have you learned about ethnicity and life expectancy?

### Reflect Your Own Personal Journey of Life

- How would you describe the experiences of the older adults in your family background that were influenced by their ethnicity, gender, and culture?

## 5 Successful Aging

LG5 Explain how to age successfully.

As we have discussed various aspects of late adulthood, it should be apparent that there are large individual differences in the patterns of change experienced by older adults. The most common pattern is *normal aging*, which characterizes most individuals (Schaie, 2016). Their psychological functioning often peaks in early midlife, plateaus until the late fifties to early sixties, then modestly declines through the early eighties, although marked decline often occurs prior to death. Another pattern involves *pathological aging*, which characterizes individuals who in late adulthood show greater than average decline. These individuals may have mild cognitive impairment in early old age, develop Alzheimer disease later, or have chronic disease that impairs their daily functioning. A third pattern of change in old age is *successful aging*, which characterizes individuals whose physical, cognitive, and socioemotional development is maintained longer than for most individuals and declines later than for most people.

For too long successful aging has been ignored (Fernandez-Ballesteros, 2019; Docking & Stock, 2018; Robine, 2019; Tkatch & others, 2017). Throughout this book, we have called attention to the positive aspects of aging. There are many robust, healthy older adults. With a proper diet, an active lifestyle, mental stimulation and flexibility, positive coping skills, good social relationships and support, and the absence of disease, many abilities can be maintained or in some cases even improved as we get older (Antonucci & Webster, 2019; Caprara & Mendoza-Ruvalcaba, 2019; Marquez-Gonzalez, Cheng, & Losada, 2019; Strandberg, 2019). Even when individuals develop a disease, improvements in medicine and lifestyle modifications mean that increasing numbers of older adults can continue to lead active, constructive lives (Santacreu, Rodriguez, & Molina, 2019). A Canadian study found that the predicted self-rated probability of aging successfully was 41 percent for those 65 to 74, 33 percent for those 75 to 84, and 22 percent for those 85+ years of age (Meng & D'Arcy, 2014). In this study, being younger, married, a regular drinker, in better health (self-perceived), and satisfied with life were associated with successful aging. Presence of disease was linked to a significant decline in predictions of successful aging. In another recent study, the following four factors emerged as best characterizing successful aging: proactive engagement, wellness resources, positive spirit, and valued relationships (Lee, Kahana, & Kahana, 2017).

Being active and engaged are especially important for successful aging (Lim & others, 2017; Mella & others, 2018; Walker, 2019). Older adults who exercise regularly, attend meetings, participate in church activities, and go on trips are more satisfied with their lives than their counterparts who disengage from society (Strandberg, 2019). Older adults who engage in challenging cognitive activities are more likely to retain their cognitive skills for a longer period of time (Calero, 2019; Cantarella & others 2017; Kinugawa, 2019; Kunzmann, 2019; Lovden, Backman, & Lindenberger, 2017; Park & Festini, 2018). Older adults who are emotionally selective, optimize their choices, and compensate effectively for losses increase their chances of aging successfully (Moss & Wilson, 2017; Nikitin & Freund, 2019; Paul, 2019). Also, a recent study of 90- to 91-year-olds found that living circumstances, especially owning one's own home and living there as long as possible; independence in various aspects of life; good health; and a good death were described as important themes of successful aging (Nosraty & others, 2015). In this study, social and cognitive aspects were thought to be more important than physical health.

Successful aging also involves perceived control over the environment (Bercovitz, Ngnoumen, & Langer, 2019; Robinson & Lachman, 2017). We have described how perceived control over the environment had a positive effect on nursing home residents' health and longevity. In recent years, the term *self-efficacy* has often been used to describe perceived control over the environment and confidence in one's ability to produce positive outcomes (Bandura, 2010, 2012, 2015). Researchers have found that many older adults are quite effective in maintaining a sense of control and have a positive view of themselves (Bercoviz, Ngnoumen, & Langer, 2019; Robinson & Lachman, 2017). Examining the positive aspects of aging is an important trend in life-span development that is likely to benefit future generations of older adults (Fernandez-Ballesteros, 2019; Carstensen, 2015b, 2016; Docking & Stock, 2018; Robine, 2019). And a very important agenda is to continue to improve our understanding of how people can live longer, healthier, more productive and satisfying lives (Mendoza-Nunez & de la Luz Martinez-Maldonado, 2019; Santacreu, Rodriguez, & Molina, 2019).

In the "Introduction" chapter we described Laura Carstensen's (2015b) recent view on the challenges and opportunities involved in the dramatic increase in life expectancy that has

### developmental connection

#### Health

Regular exercise is linked to increased longevity and prevention of many chronic diseases. Connect to "Physical Development in Late Adulthood."

Warren Buffett, one of the world's wealthiest persons (Net worth in 2018: 82 billion), is now in his late 80s and continues to stay very active, especially making high level decisions in his company. Buffett also in one of the world's most generous philanthropists, giving more than 30 billion dollars to charities.  
©Alex Wong/Getty Images

been occurring and continues to occur. In her view, the remarkable increase in the number of people living to an old age has occurred in such a short time that science, technology, and behavioral challenges have not kept pace. She proposes that the challenge is to change a world constructed mainly for young people to a world that is more compatible and supportive for the increasing number of people living to 100 and longer.

In further commentary, Carstensen (2015b, p. 70) remarked that making this change would be no small feat:

. . . parks, transportation systems, staircases, and even hospitals presume that the users have both strength and stamina; suburbs across the country are built for two parents and their young children, not single people, multiple generations or elderly people who are not able to drive. Our education system serves the needs of young children and young adults and offers little more than recreation for experienced people.

Indeed, the very conception of work as a full-time endeavor ending in the early sixties is ill suited for long lives. Arguably the most troubling is that we fret about ways the older people lack the qualities of younger people rather than exploit a growing new resource right before our eyes: citizens who have deep expertise, emotional balance, and the motivation to make a difference.

## Review Connect Reflect

**LG5** Explain how to age successfully.

### Review

- What factors are linked with aging successfully?

### Connect

- In this section, you read that self-efficacy and an optimistic attitude are linked to the happiness of centenarians. What factors play

important roles in helping people survive to extreme old age?

### Reflect Your Own Personal Journey of Life

- How might your ability to age successfully as an older adult be related to what you are doing in your life now?

## topical connections *looking forward*

In death, dying, and grieving, dying individuals and those close to them experience intense emotions. The dying individual doesn't go through a set sequence of stages, but at various points may show denial, anger, or acceptance. It is important for family and friends to communicate effectively with a dying person. In coping with the death of another person, grief may be experienced as emotional numbness, separation anxiety, despair, sadness, or loneliness. In some cases, grief may last for years. Among the most difficult losses are the death of a child or a spouse. Social support benefits widows and widowers.

## reach your learning goals

# Socioemotional Development in Late Adulthood

## 1 Theories of Socioemotional Development

Erikson's Theory

**LG1** Discuss four theories of socioemotional development and aging.

- Erikson's eighth and final stage of development, which individuals experience in late adulthood, involves reflecting on the past and either integrating it positively or concluding that one's life has not been well spent. Life review is an important theme in Erikson's stage of integrity versus despair.

Activity Theory

Socioemotional Selectivity Theory

Selective Optimization with Compensation Theory

- Activity theory states that the more active and involved older adults are, the more likely they are to be satisfied with their lives. This theory has been strongly supported by research.
- Socioemotional selectivity theory states that older adults become more selective about their social networks. Because they place a high value on emotional satisfaction, they are motivated to spend more time with familiar individuals with whom they have had rewarding relationships. Knowledge-related and emotion-related goals change across the life span, with emotion-related goals being more important when individuals get older.
- Selective optimization with compensation theory states that successful aging is linked with three main factors: (1) selection of performance domains, (2) optimization of existing capacities, and (3) compensation for deficits. These are especially likely to be relevant when loss occurs.

## 2 Personality, the Self, and Society

Personality

The Self and Society

Older Adults in Society

LG2

Describe links between personality and mortality, and identify changes in the self and society in late adulthood.

- The personality traits of conscientiousness and agreeableness increase in late adulthood. Lower levels of conscientiousness, extraversion, and openness to experience, a higher level of neuroticism, negative affect, pessimism, and a negative outlook on life are related to earlier death in late adulthood.
- In one large-scale study, self-esteem increased through most of adulthood but declined in the seventies and eighties. Further research is needed to verify these developmental changes in self-esteem. The stability of self-esteem declines in older adults. Most older adults effectively maintain a sense of self-control, although self-regulation may vary by domain. For example, older adults often show less self-regulation in the physical domain than younger adults do.
- Ageism is prejudice against others because of their age. Too many negative stereotypes of older adults continue to exist. Social policy issues in an aging society include the status of the economy and the continued viability of the Social Security system, the provision of health care, eldercare, and generational inequity.
- Of special concern are older adults who are in poverty. Poverty rates are especially high among older women who live alone and ethnic minority older adults.
- Most older adults live in the community rather than in institutions. Almost two-thirds of older adults live with family members. Older adults are less likely to have a computer in their home and less likely to use the Internet than younger adults, but they are the fastest-growing age segment of Internet users.

## 3 Families and Social Relationships

LG3

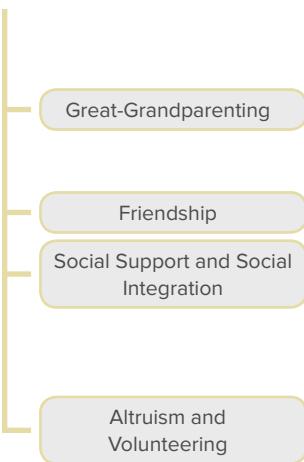

Characterize the families and social relationships of aging adults.

Lifestyle Diversity

Attachment

Older Adult Parents and Their Adult Children

- Older adult men are more likely to be married than older adult women. Retirement alters a couple's lifestyle and requires adaptation. Married older adults are often happier than single older adults. There are social, financial, and physical consequences of divorce for older adults. More divorced older adults, increased longevity, and better health have led to an increase in remarriage by older adults. Some older adults perceive negative pressure about their decision to remarry after becoming widowed or divorced, although the majority of adult children support the decision of their older adult parents to remarry. An increasing number of older adults cohabit.
- Older adults have fewer attachment relationships than younger adults; attachment anxiety decreases with increasing age; attachment security is linked to psychological and physical well-being in older adults; and insecure attachment is associated with a greater perceived negative caregiving burden in caring for people with Alzheimer disease.
- Approximately 80 percent of older adults have living children, many of whom are middle-aged. Increasingly, diversity characterizes the relationships of older parents and their adult children. Adult daughters are more likely than adult sons to be involved in the lives of aging parents. An important task that adult children can perform is to coordinate and monitor

services for an aging parent who becomes disabled. Ambivalence can characterize the relationships of adult children with their aging parents.

- Because of increased longevity, more grandparents today are also great-grandparents. One contribution of great-grandparents is knowledge of family history. One research study found that young adults have a more involved relationship with grandparents than with great-grandparents.
- There is more continuity than change in friendship for older adults.
- Social support is linked with improved physical and mental health in older adults. Older adults who participate in more organizations live longer than their counterparts who have low participation rates. Older adults often have fewer peripheral social ties but a strong motivation to spend time in relationships with close friends and family members that are emotionally rewarding.
- Altruism is linked to having a longer life. Volunteering is associated with higher life satisfaction, less depression and anxiety, better physical health, and more positive emotions.

## 4 Ethnicity, Gender, and Culture

**LG4**

Summarize how ethnicity, gender, and culture are linked with aging.

- Aging minorities cope with the double burden of ageism and racism. Nonetheless, there is considerable variation in the lives of aging minorities.
- There is stronger evidence that men become more feminine (nurturant, sensitive) as older adults than there is that women become more masculine (assertive). Older women face a double jeopardy of ageism and sexism.
- Historically, respect for older adults in China and Japan was high, but today their status is more variable. Factors that predict high status for the elderly across cultures range from their valuable knowledge to integration into the extended family.

**LG5**

Explain how to age successfully.

- Three patterns of aging are normal, pathological, and successful. Increasingly, the positive aspects of older adulthood are being studied. Factors that are linked with successful aging include an active lifestyle, positive coping skills, good social relationships and support, and the absence of disease.

### ② Defining Death and Life/Death Issues

**Learning Goal 2** Evaluate issues in determining death and decisions regarding death

Issues in Determining Death  
Decisions Regarding Life, Death, and Health Care

### ③ A Developmental Perspective on Death

**Learning Goal 3** Discuss death and attitudes about it at different points in development

Causes of Death  
Attitudes Toward Death at Different Points in the Life Span

### ④ Facing One's Own Death

**Learning Goal 4** Explain the psychological aspects involved in facing one's own death and the contexts in which people die

Kübler-Ross' Stages of Dying  
Perceived Control and Denial  
The Contexts in Which People Die

### ⑤ Coping with the Death of Someone Else

**Learning Goal 5** Identify ways to cope with the death of another person

Communicating with a Dying Person  
Grieving  
Making Sense of the World  
Losing a Life Partner  
Forms of Mourning

**P**aige Farley-Hackel and her best friend Ruth McCourt teamed up to take McCourt's 4-year-old daughter, Juliana, to Disneyland. They were originally booked on the same flight from Boston to Los Angeles, but McCourt decided to use her frequent flyer miles and go on a different airplane. Both their flights exploded 17 minutes apart after terrorists hijacked them, then rammed them into the twin towers of the World Trade Center in New York City on 9/11/2001.

Forty-five-year-old Ruth McCourt was a homemaker from New London, Connecticut, who had met Farley-Hackel at a day spa she used to own in Boston. McCourt gave up the business when she married, but the friendship between the two women lasted. They often traveled together and shared their passion for reading, cooking, and learning.

Forty-six-year-old Farley-Hackel was a writer, motivational speaker, and spiritual counselor who lived in Newton, Massachusetts. She was looking forward to the airing of the first few episodes of her new radio program, "Spiritually Speaking," and wanted to eventually be on The Oprah Winfrey Show, said her husband, Allan Hackel. Following 9/11, Oprah provided a memorial tribute to Farley-Hackel, McCourt, and Juliana.

## topical connections *looking back* -----

In the United States, the leading cause of death in infancy is sudden infant death syndrome (SIDS). In early childhood, motor vehicle accidents are the leading cause of death, followed by cancer and cardiovascular disease. Injuries are the leading cause of death during middle and late childhood, and the most common cause of severe injury and death in this period is motor vehicle accidents, either as a pedestrian or as a passenger. The three leading causes of death in adolescence are accidents, homicide, and suicide. Emerging adults have more than twice the mortality rate of adolescents. For many years, heart disease was the leading cause of death in middle adulthood, followed by cancer; however, since 2005 more individuals 45 to 64 years of age in the United States die of cancer, followed by cardiovascular disease. Men have higher mortality rates than women for all of the leading causes of death. Nearly 60 percent of deaths among 65- to 74-year-old U.S. adults are caused by cancer or cardiovascular disease, with cancer now the leading cause of death. However, in the age groups of 75 to 84 and 85 and over, cardiovascular disease is the leading cause of death.

# preview

In this final chapter, we will explore many aspects of death and dying. Among the questions that we will ask are these: What characterizes the death system, and what are its cultural and historical contexts? How can death be defined? What are some links between development and death? How do people face their own death? How do individuals cope with the death of someone they love?

## 1 The Death System and Cultural Contexts

LG1

Describe the death system and its cultural and historical contexts.

The Death System and Its Cultural Variations

Changing Historical Circumstances

Today in the United States, deaths of older adults account for approximately two-thirds of the 2 million deaths that occur each year. Thus, what we know about death, dying, and grieving mainly is based on information about older adults. Youthful death is far less common. What has changed historically in the United States is when, where, and how people die. And how we deal with death is part of our culture. Every culture has a death system, and variations in this death system occur across cultures.

### THE DEATH SYSTEM AND ITS CULTURAL VARIATIONS

Robert Kastenbaum (1932–2013) emphasizes that the *death system* in any culture comprises the following components (Kastenbaum 2009, 2012):

- *People*. Because death is inevitable, everyone is involved with death at some point, either their own death or the death of others. Some individuals have a more systematic role with death, such as those who work in the funeral industry and the clergy, as well as people who work in life-threatening contexts such as firefighters and police officers.
- *Places or contexts*. These include hospitals, funeral homes, cemeteries, hospices, battlefields, and memorials (such as the Vietnam Veterans Memorial wall in Washington, DC).
- *Times*. Death involves times or occasions, such as Memorial Day in the United States and the Day of the Dead in Mexico, which are times to honor those who have died. Also, anniversaries of disasters such as D-Day in World War II, 9/11/2001, and Hurricane Sandy in 2012, as well as the 2004 tsunami in Southeast Asia that took approximately 100,000 lives, are times when those who died are remembered in special ways such as ceremonies.
- *Objects*. Many objects in a culture are associated with death, including caskets and clothes, armbands, and hearses in specific colors. In the United States black is associated with death, but in China white is linked to death.
- *Symbols*. Symbols such as a skull and crossbones, as well as last rites in the Catholic religion and various religious ceremonies, are connected to death.

In 2017, Hurricane Harvey wreaked havoc on Houston, Texas, causing 125 billion dollars in damages. At least 88 people died as a result of the devastating hurricane.

©Steve Gonzales/Houston Chronicle/AP Images

Cultural variations characterize death and dying (Butters, 2017; Guilbeau, 2018; Miller, 2016; Prince, 2018; Wang & others, 2018; Whitehouse, 2018). To live a full life and die with glory was the prevailing goal of the ancient Greeks. Individuals are more conscious of death in times of war, famine, and plague. Whereas Americans are conditioned from early in life to live as though they were immortal, in much of the world this fiction cannot be maintained. Death crowds the streets of Mumbai in daily overdisplay, as it does in the impoverished towns of

Bangladesh. By contrast, in the United States it is not uncommon to reach adulthood without having talked about death or experienced the death of someone close.

Most societies throughout history have had philosophical or religious beliefs about death, and most societies have a ritual that deals with death (Ahluwalia & Mohabir, 2018; Ballinger & others, 2017; Jones & Nie, 2018; Pun & others, 2018; Schweda & others, 2017). Death may be seen as a punishment for one's sins, an act of atonement, or a judgment from a just God. For some, death means loneliness; for others, death is a quest for happiness. For still others, death represents redemption, a relief from the trials and tribulations of the earthly world. Some embrace death and welcome it; others abhor and fear it. For those who welcome it, death may be seen as the fitting end to a fulfilled life. From this perspective, how we depart from Earth is influenced by how we have lived.

In most societies, death is not viewed as the end of existence—after the biological body has died, the spiritual body is believed to live on (Hamilton & others, 2018; Inbadas, 2017). This religious perspective is favored by most Americans as well (Gowan, 2003). Cultural variations in attitudes toward death include belief in reincarnation, which is an important aspect of the Hindu and Buddhist religions (Agoramoorthy & Hsu, 2017; Setta & Shemie, 2015). In the Gond culture of India, death is believed to be caused by magic and demons. The members of the Gond culture react angrily to death. In the Tanala culture of Madagascar, death is believed to be caused by natural forces. The members of the Tanala culture show a much more peaceful reaction to death than members of the Gond culture. Figure 1 shows a ritual associated with death in South Korea.

In many ways, we in the United States are death avoiders and death deniers (Norouzieh, 2005). This denial can take many forms, including our persistent search for a fountain of youth through diet, surgery, and other means, as well as the tendency of the funeral industry to gloss over death and fashion lifelike qualities in the dead.

### developmental connection

#### Life Expectancy

The upper boundary of the human life span is 122 years of age (based on the oldest age documented). Connect to “Introduction.”

## CHANGING HISTORICAL CIRCUMSTANCES

One historical change involves the age group in which death most often occurs. Two hundred years ago, almost one of every two children died before the age of 10, and one parent died before children grew up. Today, death occurs most often among older adults (Carr, 2009). Life expectancy has increased from 47 years for a person born in 1900 to 79 years for someone born today (U.S. Census Bureau, 2017). Today, the life expectancy in the U.S. for women is 81, for men 76. In 1900, most people died at home, cared for by their family. As our population has aged and become more mobile, greater numbers of older adults die apart from their families (Carr, 2009). In the United States today, more than 80 percent of all deaths occur in institutions or hospitals. The care of a dying older person has shifted away from the family and minimized our exposure to death and its painful surroundings (Gold, 2011).

### Review Connect Reflect

**LG1** Describe the death system and its cultural and historical contexts.

#### Review

- What characterizes the death system in a culture? What are some cultural variations in the death system?
- What are some changing sociohistorical circumstances regarding death?

#### Connect

- You just read about how changes in life expectancy over time have

affected our experience of death.

In earlier chapters, what did you learn about life expectancy and the age span that encompasses older adulthood?

#### Reflect Your Own Personal Journey of Life

- How extensively have death and dying been discussed in your family? Explain.

## 2 Defining Death and Life/Death Issues

Issues in Determining Death

LG2

Evaluate issues in determining death and decisions regarding death.

Decisions Regarding Life, Death, and Health Care

Is there one point in the process of dying that is the point at which death takes place, or is there a gradual transition between life and death? What are some decisions individuals can make about life, death, and health care?

### ISSUES IN DETERMINING DEATH

What are some issues in determining death?  
©Dario Mitidieri/Getty Images

Thirty years ago, determining whether someone was dead was simpler than it is today. The end of certain biological functions, such as breathing and blood pressure, and the rigidity of the body (rigor mortis) were considered to be clear signs of death. In recent decades, defining death has become more complex (Ganapathy, 2018; Greer & others, 2016; Johnson, 2017; Hammand & others, 2017).

**Brain death** is a neurological definition of death which states that a person is brain dead when all electrical activity of the brain has ceased for a specified period of time. A flat EEG (electroencephalogram) reading for a specified period of time is one criterion of brain death. The higher portions of the brain often die sooner than the lower portions. Because the brain's lower portions monitor heartbeat and respiration, individuals whose higher brain areas have died may continue to breathe and have a heartbeat (MacDougall & others, 2014). The definition of brain death currently followed by most physicians includes the death of both the higher cortical functions and the lower brain stem functions (Oliva & others, 2017; Waweru-Silka & others, 2017).

Some medical experts argue that the criteria for death should include only higher cortical functioning. If the cortical death definition were adopted, then physicians could declare that a person is dead when there is no cortical functioning in that person, even though the lower brain stem is functioning. Supporters of the cortical death policy argue that the functions we associate with being human, such as intelligence and personality, are located in the higher cortical part of the brain. They believe that when these functions are lost, the "human being" is no longer alive.

### DECISIONS REGARDING LIFE, DEATH, AND HEALTH CARE

In cases of catastrophic illness or accidents, patients might not be able to respond adequately to participate in decisions about their medical care. To prepare for this situation, some individuals make choices earlier.

**Advance Care Planning** *Advance care planning* refers to the process of patients thinking about and communicating their preferences about end-of-life care (Koss & Baker, 2016; Pereira-Salgado & others, 2018; Rietjens & others, 2017; Sulmasy, 2018). For many patients in a coma, it is not clear what their wishes regarding termination of treatment might be if they still were conscious (Abu Snineh, Camicioli, & Miysaki, 2017). One study found that advance care planning decreased life-sustaining treatment, increased hospice use, and decreased hospital use (Brinkman-Stoppeleburg, Rietjens, & van der Heide, 2014). Another recent study revealed that completion of an advance directive was associated with a lower probability of receiving life-sustaining treatments (Yen & others, 2017). Recognizing that some terminally ill patients might prefer to die rather than linger in a painful or vegetative state, the organization "Choice in Dying" created the *living will*, a legal document that reflects the patient's advance care planning. A study of older adults found that advance care planning was associated with improved quality of care at the end of life, including less in-hospital death and greater use of hospice care (Bischoff & others, 2013).

Physicians' concerns over malpractice suits and the efforts of people who support the living will concept have produced natural death legislation. Laws in all 50 states now accept an *advance directive* such as a living will (Mitchell & Dale, 2016; Olsen, 2016). An advance directive must be signed while the individual still is able to think clearly (Myers & others, 2018; Shin & others, 2016). A study of end-of-life planning revealed that only 15 percent of patients 18 years of age and older had a living will (Clements, 2009). A research review concluded that physicians have a positive attitude toward advance directives (Coleman, 2013).

**brain death** A neurological definition of death. A person is brain dead when all electrical activity of the brain has ceased for a specified period of time. A flat EEG recording is one criterion of brain death.

Recently, Physician Orders for Life-Sustaining Treatment (POLST), a document that is more specific than previous advance directives, was created (Hopping-Winn & others, 2018; Lammers & others, 2018; Moss & others, 2017; Struck, Brown & Madison, 2017). POLST translates treatment preferences into medical orders such as those involving cardiopulmonary resuscitation, extent of treatment, and artificial nutrition via a tube (Mayoral & others, 2018; Scotti, 2016; Stuart & Thielke, 2017). POLST involves the health-care professional and the patient or surrogate conferring to determine and state the wishes of the patient. POLST is currently available or being considered in 34 states.

**Euthanasia** Euthanasia (“easy death”) is the act of painlessly ending the lives of individuals who are suffering from an incurable disease or severe disability (Kanniyakonil, 2018; Miller, Dresser, & Kim, 2018; Preston, 2018; Radbruch & others, 2016; Savulescu, 2017). Sometimes euthanasia is called “mercy killing.” Euthanasia also involves the physician or a third party administering the lethal medication. Euthanasia is legal in Belgium, Colombia, the Netherlands, and Luxembourg, but is not legal in the United States. Distinctions are made between two types of euthanasia: passive and active.

- **Passive euthanasia** occurs when a person is allowed to die by withholding available treatment, such as withdrawing a life-sustaining device. For example, this might involve turning off a respirator or a heart-lung machine.
- **Active euthanasia** occurs when death is deliberately induced, as when a lethal dose of a drug is injected.

Technological advances in life-support devices raise the issue of quality of life (Dean, 2017; Goligher & others, 2017; Jouffre & others, 2018). Nowhere was this more apparent than in the highly publicized case of Terri Schiavo, who suffered severe brain damage related to cardiac arrest and a lack of oxygen to the brain. She went into a coma and spent 15 years in a vegetative state. Across the 15 years, the question of whether passive euthanasia should be implemented or whether she should be kept in the vegetative state with the hope that her condition might change for the better was debated between family members and eventually at a number of levels in the judicial system. At one point toward the end of her life in the early spring of 2005, a court ordered that her feeding tube be removed. However, subsequent appeals led to its reinsertion twice. The feeding tube was removed a third and final time on March 18, 2005, and she died 13 days later.

Should individuals like Terri Schiavo be kept alive in a vegetative state? The trend is toward acceptance of passive euthanasia in the case of terminally ill patients (Hurst & Mauron, 2017; Sannita, 2017).

The inflammatory argument that once equated this practice with suicide rarely is heard today. However, experts do not yet entirely agree on the precise boundaries or the exact mechanisms by which treatment decisions should be implemented (Jouffre & others, 2018; Lum & others, 2017; Porteri, 2018). Can a comatose patient’s life-support systems be disconnected when the patient has left no written instructions to that effect? Does the family of a comatose patient have the right to overrule the attending physician’s decision to continue life-support systems? These questions have no simple or universally agreed-upon answers (Chen & Azueta, 2017).

**Assisted suicide** requires the patient to self-administer the lethal medication and to determine when and where to do this, whereas active euthanasia involves the physician or a third party administering the lethal medication (Hosie, 2018; Miller & Appelbaum, 2018; Vandenberghe, 2018). The most widely publicized assisted suicides were carried out by Jack Kevorkian, a Michigan physician, who assisted a number of terminally ill patients in ending their lives. After a series of trials, Kevorkian was convicted of second-degree murder and given a 10- to 15-year sentence. He was released from prison at age 79 for good behavior in June 2007 and promised not to participate in any further assisted suicides. Kevorkian died in 2011 at the age of 83.

Assisted suicide is now legal in Belgium, Canada, Finland, Luxembourg, the Netherlands, and Switzerland. The United States government has no official policy on assisted suicide and leaves the decision up to each of the states. An increasing number of states now allow assisted suicide: California, Colorado, Montana, Oregon, Vermont, and Washington, as well as

Terri Schiavo (right) shown with her mother. *What issues did the Terri Schiavo case raise?* ©Stringer/Getty Images

**euthanasia** The act of painlessly ending the lives of persons who are suffering from incurable diseases or severe disabilities; sometimes called “mercy killing.” In euthanasia, the physician or a third party administers the lethal medication (active euthanasia) or withdraws life-sustaining treatments.

**passive euthanasia** The withholding of available treatments, such as life-sustaining devices, in order to allow a person to die.

**active euthanasia** Death induced deliberately, as by injecting a lethal dose of a drug.

**assisted suicide** Requires the patient to self-administer the lethal medication, and the patient is allowed to decide when and where to do this.

Washington, DC. Assisted suicide involves the physician giving the patient an overdose of muscle relaxants or sedatives to take, which causes a coma and then death. In states where assisted suicide is illegal, the crime is typically considered manslaughter or a felony.

Even in places where assisted suicide is legal, it is not a common practice. A research review revealed that the percentage of physician-assisted deaths ranged from 0.1 to 0.2 percent in the United States and Luxembourg to 1.8 to 2.9 percent in the Netherlands (Steck & others, 2013). In this review, the percentage of assisted suicide cases reported to authorities has increased in recent years and the individuals who die through assisted suicide are most likely to be males from 60 to 75 years of age.

To what extent do people in the United States think euthanasia and assisted suicide should be legal? A recent Gallup poll found that 69 percent of U.S. adults said euthanasia should be legal, 51 percent said they would consider ending their own lives if faced with a terminal illness, and 50 percent reported that physician-assisted suicide is morally acceptable (Swift, 2016).

Why is euthanasia so controversial? Those in favor of euthanasia argue that death should be calm and dignified, not full of agony, pain, and prolonged suffering. Those against euthanasia stress that it is a criminal act of murder in most states in the United States and in most other countries. Many religious individuals, especially Christians, say that taking a life for any reason is against God's will and is an act of murder.

**Needed: Better Care for Dying Individuals** In the United States, the process of dying is often lonely, prolonged, and painful. Dying individuals often get too little or too much care. Scientific advances sometimes have made dying harder by delaying the inevitable. And even though effective painkillers are available, too many people experience severe pain during their last days and months of life (Buiting & de Graas, 2018; Chi & others, 2018; Hughes, Volicer, & van der Steen, 2018; Montague & others, 2017). A recent study found that 61 percent of dying patients were in pain in the last year of life and that nearly one-third had symptoms of depression and confusion prior to death (Singer & others, 2015).

Many health-care professionals have not been trained to provide adequate end-of-life care or to understand its importance. One study revealed that in many cases doctors don't give dying patients adequate information about how long they are likely to live or how various treatments will affect their lives (Harrington & Smith, 2008). For example, in this study of patients with advanced cancer, only 37 percent of doctors told patients how long they were likely to live.

Care providers are increasingly interested in helping individuals experience a "good death" (Flaskerud, 2017; Tenzek & Depner, 2017). One view is that a good death involves physical comfort, support from loved ones, acceptance, and appropriate medical care (Krishnan, 2017). For some individuals, a good death involves accepting one's impending death and not feeling like a burden to others (Carr, 2009). In a recent review, the three most frequent themes described in articles on a good death involved (1) preference for dying process (94 percent of reports), (2) pain-free status (81 percent), and (3) emotional well-being (64 percent) (Meier & others, 2016).

Recent criticisms of the "good death" concept emphasize that death itself has shifted from being an event at a single point in time to a process that takes place over years and even decades (Pollock & Seymour, 2018; Smith & Periyakoli, 2018). Thus, say the critics, we need to move away from the concept of a "good death" as a specific event for an individual person to a larger vision of a world that not only meets the needs of individuals at their moment of death but also focuses on making their lives better during their final years and decades.

**Hospice** is a program committed to making the end of life as free from pain, anxiety, and depression as possible (Fridman & others, 2018; Wang & others, 2017). Traditionally, a hospital's goals have been to cure illness and prolong life (Koksvik, 2018). By contrast, hospice care emphasizes **palliative care**, which involves reducing pain and suffering and helping individuals die with dignity (Bangerter & others, 2018; Chi & others, 2018; Cox & Curtis, 2016; Nilsen & others, 2018; Pidgeon & others, 2017). However, U.S. hospitals recently have rapidly expanded their provision of palliative care. One study found that more than 85 percent of mid- to large-size U.S. hospitals have a palliative care team (Morrison, 2013). Hospice-care professionals work together to treat the dying person's symptoms, make the individual as comfortable as possible, show interest in the patient and his or her family, and help everyone involved cope with death (Bogusz, Pekacka-Falkowska, & Magowska, 2018; Levy & others, 2016; Stiel & others, 2018; Wise, 2017).

What characterizes hospice care?  
©Comstock Images/PictureQuest

**hospice** A program committed to making the end of life as free from pain, anxiety, and depression as possible. The goals of hospice contrast with those of a hospital, which are to cure disease and prolong life.

**palliative care** The type of care emphasized in a hospice, which involves reducing pain and suffering and helping individuals die with dignity.

## connecting with careers

### Kathy McLaughlin, Home Hospice Nurse

Kathy McLaughlin is a home hospice nurse in Alexandria, Virginia. She provides care for individuals with terminal cancer, Alzheimer disease, and other diseases. There currently is a shortage of home hospice nurses in the United States.

McLaughlin says that she has seen too many people dying in pain, away from home, hooked up to needless machines. In her work as a home hospice nurse, she comments,

“I know I’m making a difference. I just feel privileged to get the chance to meet this person who is not going to be around much longer. I want to enjoy the moment with this person. And I want them to enjoy the moment. They have great stories. They are better than novels.” (McLaughlin, 2003, p. 1)

Kathy McLaughlin with her hospice patient Mary Monteiro.  
Courtesy of the family of Mary Monteiro

A primary hospice goal is to bring pain under control and to help dying patients face death in a psychologically healthy way (Chi & others, 2017; West & others, 2018). The hospice also makes every effort to include the dying individual’s family; it is believed that this strategy benefits not only the dying individual but family members as well, probably diminishing their guilt after the death.

The hospice movement has grown rapidly in the United States. More than 1,500 community groups are involved nationally in establishing hospice programs. Hospices are more likely to serve people with terminal cancer than those with other life-threatening conditions (Kastenbaum, 2012). Hospice advocates emphasize the advantages of controlling pain for dying individuals and creating an environment for the patient that is superior to that found in most hospitals (West & others, 2016). For hospice services to be covered by Medicare, a patient must be deemed by a physician to have six months or fewer to live. Also, some hospice providers will provide care only if the patient has a family caregiver living in the home (or nearby).

Approximately 90 percent of hospice care is provided in patients’ homes (Hayslip & Hansson, 2007). In some cases, home-based care is provided by community-based health-care professionals or volunteers; in other cases, home-based care is provided by home health-care agencies or Visiting Nurse Associations (Abrahamson, Davila, & Hountz, 2018). There is a rapidly growing need for competent home health aides in hospice and palliative care (Anthony, 2018; Boerner, Gleason, & Barooah, 2016; Feldman & others, 2018; Franzosa, Tsui, & Baron, 2018; Ghesquiere & Bagaajav, 2018; Nisbet & Morgan, 2018; Quinn & others, 2016). Also, some hospice care is provided in free-standing, full-service hospice facilities and in hospice units in hospitals. To read about the work of a home hospice nurse, see *Connecting with Careers*.

### 3 A Developmental Perspective on Death

LG3

Discuss death and attitudes about it at different points in development.

Causes of Death

Attitudes Toward Death at Different Points in the Life Span

Do the causes of death vary across the life span? Do we have different expectations and attitudes about death at different stages of our development?

## CAUSES OF DEATH

### developmental connection

#### Conditions, Diseases, and Disorders

Nearly 3,000 deaths of infants per year in the United States are attributed to SIDS. Connect to “Physical Development in Infancy.”

Death can occur at any point in the human life span. Death can occur during prenatal development through miscarriages or stillborn births. Death can also occur during the birth process or in the first few days after birth, which usually happens because of a birth defect or because infants have not developed adequately to sustain life outside the uterus. Earlier we described *sudden infant death syndrome (SIDS)*, in which infants stop breathing, usually during the night, and die without apparent cause (Carlin & Moon, 2017; Siren, 2017). SIDS currently is the leading cause of infant death in the United States, with the risk highest at 2 to 4 months of age (NICHD, 2018).

In childhood, death occurs most often because of accidents or illness. Accidental death in childhood can be the consequence of events such as an automobile accident, drowning, poisoning, fire, or a fall from a high place. Major illnesses that cause death in children are heart disease, cancer, and birth defects.

Compared with childhood, death in adolescence is more likely to occur because of motor vehicle accidents, suicide, and homicide. Many motor vehicle accidents that cause death in adolescence are alcohol-related. We will examine suicide in greater depth shortly.

Older adults are more likely to die from chronic ailments such as heart disease and cancer, whereas younger adults are more likely to die from accidents. Older adults' diseases often incapacitate before they kill, which produces a course of dying that slowly leads to death. Of course, many young and middle-aged adults also die of heart disease, cancer, and other diseases.

## ATTITUDES TOWARD DEATH AT DIFFERENT POINTS IN THE LIFE SPAN

The ages of children and adults influence the way they experience and think about death. A mature, adult-like conception of death includes an understanding that death is final and irreversible, that death represents the end of life, and that all living things die. Most researchers have found that as children grow, they develop a more mature approach to death (Yang & Park, 2017).

**Childhood** Researchers have found that children's conception of death changes as they develop but that even young children begin to develop views of death that are more cognitively advanced than was previously thought (Rosengren, Gutierrez, & Schein, 2014a, b) For example, a recent study found that as early as 4 to 5 years of age, many young children understand the irreversibility of death and that it involves the cessation of mental and physical functioning (Panagiotaki & others, 2018). At some point in the middle and late childhood years, many children develop more realistic and accurate perceptions of death, such as increasingly viewing its cause as biological in nature (Panagiotaki & others, 2018).

Children's views of death and their experiences with death vary with the contexts and cultures in which they grow up. As we indicated earlier in this chapter, U.S. children are not exposed to death nearly as much as children in some cultures. In one study, researchers found that higher-SES non-Latino White parents were likely to shield their children from death, while immigrant Mexican American parents thought it was important for their children to learn about death and talk about it (Gutierrez, Rosengren, & Miller, 2014).

The death of a parent is especially difficult for children (Bergman, Axberg, & Hanson, 2017; Greene & McGovern, 2017). When a child's parent dies, the child's school performance and peer relationships often suffer. For some children, as well as adults, a parent's death can be

devastating and result in a hypersensitivity about death, including a fear of losing others close to the individual. In some cases, loss of a sibling can result in similar negative outcomes (Sood & others, 2006). However, a number of factors, such as the quality of the relationship and type of the death (whether due to an accident, long-standing illness, suicide, or murder, for example), can influence the individual's development following the death of a person close to the individual.

Most psychologists emphasize that honesty is the best strategy in discussing death with children. Treating the concept as unmentionable is thought to be an inappropriate strategy, yet most of us have grown up in a society where death is rarely discussed.

In addition to honesty, the best response to a child's query about death might depend on the child's maturity level. For example, a preschool child requires a less elaborate explanation than an older child. Death can be explained to preschool children in simple physical and biological terms. Actually, what young children need more than elaborate explanations of death is reassurance that they are loved and will not be abandoned. Regardless of children's ages, adults should be sensitive and sympathetic, encouraging them to express their own feelings and ideas.

Also, support programs for parentally bereaved children and their caregivers can be beneficial. In a recent research review, it was concluded that relatively brief interventions can prevent children from developing severe problems, such as traumatic grief and mental disorders (Bergman, Axberg, & Hanson, 2017). One of the most successful programs is the Family Bereavement Program, a 12-session program designed to promote effective parenting and teach coping skills following the death of a parent or caregiver. In a recent experimental study, children and adolescents who participated in the program showed better adjustment up to 6 years following the program (Sandler & others, 2017). In addition, bereaved parents who participated in the program had lower levels of depression, were less likely to have prolonged grief disorders, less likely to have alcohol problems, and have better coping skills up to 6 years after participating in the program (Sandler & others, 2016).

**Adolescence** Deaths of peers, friends, siblings, parents, grandparents, or great-grandparents bring death to the forefront of adolescents' lives. Adolescents develop more abstract conceptions of death than children do. For example, adolescents describe death in terms of darkness, light, transition, or nothingness (Wenestam & Wass, 1987). They also develop religious and philosophical views about the nature of death and whether there is life after death.

**Adulthood** A recent study of young adults and middle-aged adults found that women had more difficulty than men in adjusting to the death of a parent and also that women had a more intense grief response to a parent's death (Hayslip, Pruett, & Caballero, 2015). There is no evidence that a special orientation toward death develops in early adulthood. An increase in consciousness about death accompanies individuals' awareness that they are aging, which usually intensifies in middle adulthood. In our discussion of middle adulthood, we indicated that midlife is a time when adults begin to think more about how much time is left in their lives. Researchers have found that middle-aged adults actually fear death more than do young adults or older adults (Kalish & Reynolds, 1976). Older adults, though, think about death more and talk about it more in conversation with others than do middle-aged and young adults. They also have more direct experience with death as their friends and relatives become ill and die. Older adults are forced to examine the meanings of life and death more frequently than are younger adults.

In old age, one's own death may take on an appropriateness it lacked in earlier years. Increased thinking and conversing about death, and an increased sense of integrity resulting from a positive life review, may help older adults accept death. Older adults are less likely to have unfinished business than are younger adults. They usually do not have children who need to be guided to maturity, their spouses are more likely to be dead, and they are less likely to have work-related projects that require completion. Lacking such anticipations, death may be less emotionally painful to them than to young or middle-aged adults. Even among older adults, however, attitudes toward death vary (Whitbourne & Meeks, 2011).

## 4 Facing One's Own Death

Kübler-Ross' Stages of Dying

Sustained and soothed by an unfaltering trust, approach thy grave,  
Like one who wraps the drapery of his couch  
About him, and lies down to pleasant dreams.

—WILLIAM CULLEN BRYANT  
*American Poet, 19th Century*

**LG4** Explain the psychological aspects involved in facing one's own death and the contexts in which people die.

Perceived Control and Denial

The Contexts in Which People Die

Knowledge of death's inevitability permits us to establish priorities and structure our time accordingly. As we age, these priorities and structurings change in recognition of diminishing future time. Values concerning the most important uses of time also change. For example, when asked how they would spend their six remaining months of life, younger adults described such activities as traveling and accomplishing things they previously had not done; older adults described more inner-focused activities—contemplation and meditation, for example (Kalish & Reynolds, 1976).

Most dying individuals want an opportunity to make some decisions regarding their own life and death (Kastenbaum, 2012). Some individuals want to complete unfinished business; they want time to resolve problems and conflicts and to put their affairs in order.

### KÜBLER-ROSS' STAGES OF DYING

We are all born to die, and our lives prepare us for that finality. Dealing with our own death usually becomes the focal point in our life only when we are nearing death, but we live with an awareness of death throughout our lives. However, as indicated earlier in the chapter, people (especially in the United States) often try to avoid thinking about death in any way.

Might there be a sequence of stages we go through as we face death? Elisabeth Kübler-Ross (1969) divided the behavior and thinking of dying persons into five stages: denial and isolation, anger, bargaining, depression, and acceptance.

**Denial and isolation** is Kübler-Ross' first stage of dying, in which the person denies that death is really going to take place. The person may say, "No, it can't be me. It's not possible." This is a common reaction to a diagnosis of terminal illness. However, denial is usually only a temporary defense. It is eventually replaced with increased awareness when the person is confronted with such matters as financial considerations, unfinished business, and worry about the well-being of surviving family members.

**Anger** is Kübler-Ross' second stage of dying, in which the dying person recognizes that denial can no longer be maintained. Denial often gives way to anger, resentment, rage, and envy. The dying person's question becomes "Why me?" At this point, the person becomes increasingly difficult to care for as anger may become displaced and projected onto physicians, nurses, family members, and even God. The realization of loss is great, and those who symbolize life, energy, and competent functioning are especially salient targets of the dying person's resentment and jealousy.

**Bargaining** is Kübler-Ross' third stage of dying, in which the person develops the hope that death can somehow be postponed or delayed. Some persons enter into a bargaining or negotiation—often with God—as they try to delay their death. Psychologically, the person is saying, “Yes, me, but . . .” In exchange for a few more days, weeks, or months of life, the person promises to lead a reformed life dedicated to God or to the service of others.

**Depression** is Kübler-Ross' fourth stage of dying, in which the dying person comes to accept the certainty of death. At this point, a period of depression or preparatory grief may appear. The dying person may become silent, refuse visitors, and spend much of the time crying or grieving. This behavior is normal and is an effort to disconnect the self from love objects. Attempts to cheer up the dying person at this stage should be discouraged, says Kübler-Ross, because the dying person has a need to contemplate impending death.

**Acceptance** is Kübler-Ross' fifth stage of dying, in which the person develops a sense of peace, an acceptance of his or her fate, and in many cases, a desire to be left alone. In this stage, feelings and physical pain may be virtually absent. Kübler-Ross describes this fifth stage as the end of the dying struggle, the final resting stage before death. A summary of Kübler-Ross' dying stages is presented in Figure 2.

What is the current evaluation of Kübler-Ross' theory? According to Robert Kastenbaum (2009, 2012), there are some problems with Kübler-Ross' approach:

- The existence of the five-stage sequence has not been demonstrated by either Kübler-Ross or independent research.
- The five-stage interpretation neglected the patients' situations, including relationship support, specific effects of illness, family obligations, and institutional climate in which they were interviewed.

Despite these shortcomings, however, Kübler-Ross' pioneering efforts were important in calling attention to the needs of people who are attempting to cope with life-threatening illnesses. She did much to encourage attention to the quality of life for dying persons and their families.

Because of the criticisms of Kübler-Ross' stages, some psychologists prefer to describe them not as stages but as potential reactions to dying. At any one moment, a number of emotions may wax and wane. Hope, disbelief, bewilderment, anger, and acceptance may come and go as individuals try to make sense of what is happening to them (Renz & others, 2013).

In facing their own death, some individuals struggle until the end, desperately trying to hang on to their lives. Acceptance of death never comes for them. Some psychologists believe that the harder individuals fight to avoid the inevitable death they face and the more they deny it, the more difficulty they will have in dying peacefully and in a dignified way; other psychologists argue that not confronting death until the end may be adaptive for some individuals (Lifton, 1977).

The extent to which people have found meaning and purpose in their lives is linked with how they approach death (Balon & Morreale, 2016; Kalanithi, 2016). One study revealed that individuals with a chronic, life-threatening illness—congestive heart failure—were trying to find meaning in life (Park & others, 2008). In another study, individuals with less than three months to live who had found purpose and meaning in their lives felt the least despair in their final weeks, whereas dying individuals who saw no reason for living were the most distressed and wanted to hasten death (McClain, Rosenfeld, & Breitbart, 2003). In this and other studies, spirituality helped to buffer dying individuals from severe depression (Park, 2012a, b). Researchers also have found that the closer critically ill patients get to death the more religious they become (Park, 2010).

## PERCEIVED CONTROL AND DENIAL

Perceived control may work as an adaptive strategy for some older adults who face death. When individuals are led to believe they can influence and control events—such as prolonging their lives—they may become more alert and cheerful. Giving nursing home residents options for control improved their attitudes and increased their longevity (Rodin & Langer, 1977).

Denial also may be a fruitful way for some individuals to approach death. It can be adaptive or maladaptive (Cottrell & Duggleby, 2016). Denial can be used to avoid the destructive impact

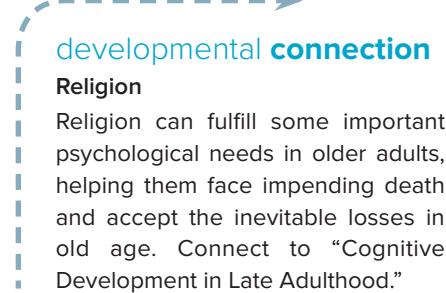

**FIGURE 2**

### KÜBLER-ROSS' STAGES OF DYING.

According to Elisabeth Kübler-Ross, we go through five stages of dying: denial and isolation, anger, bargaining, depression, and acceptance. Does everyone go through these stages, and do we go through them in the same order? Explain.

©Science Photo Library/Getty Images

Man is the only animal that finds his own existence a problem he has to solve and from which he cannot escape. In the same sense man is the only animal who knows he must die.

—ERICH FROMM

What are some positive and negative aspects of dying at home compared with dying in a hospital?

©Photodisc/Getty Images

of shock by delaying the necessity of dealing with one's death. Denial can insulate the individual from having to cope with intense feelings of anger and hurt; however, if denial keeps us from undergoing a life-saving operation, it clearly is maladaptive. Denial is neither good nor bad; its adaptive qualities need to be evaluated on an individual basis.

## THE CONTEXTS IN WHICH PEOPLE DIE

For dying individuals, the context in which they die is important (Hemati & others, 2016; Thompson & others, 2016). More than 50 percent of Americans die in hospitals and nearly 20 percent die in nursing homes. Some people, though, spend their final days in isolation and fear. An increasing number of people choose to die in the humane atmosphere of a hospice (Fridman & others, 2018; Wang & others, 2017). A Canadian study found that 71 percent of adults preferred to be at home if they were near death, 15 percent preferred to be in a hospice/palliative care facility, 7 percent preferred to be in a hospital, and only 2 percent preferred to be in a nursing home (Wilson & others, 2013).

Hospitals offer several important advantages to the dying individual; for example, professional staff members are readily available, and the medical technology present may prolong life. But a hospital may not be the best place for many people to die. Most individuals say they would rather die at home (Bannon & others, 2018; Carr & Luth, 2016). Many feel, however, that they will be a burden at home, that space is inadequate there, and that dying at home may alter relationships. Individuals who are facing death also worry about the competency of caregivers and availability of emergency medical treatment if they remain at home.

## 5 Coping with the Death of Someone Else

Communicating with a Dying Person

Grieving

Making Sense of the World

**LG5** Identify ways to cope with the death of another person.

Losing a Life Partner

Forms of Mourning

Loss can come in many forms in our lives—divorce, a pet's death, being fired from a job—but no loss is greater than that which comes through the death of someone we love and care for, such as a parent, sibling, spouse, relative, or friend. In the ratings of life's stresses that require the most adjustment, death of a spouse is given the highest number. How should we communicate with a dying individual? How can we cope with the death of someone we love?

## COMMUNICATING WITH A DYING PERSON

Most psychologists argue that it is best for dying individuals to know that they are dying and for significant others to know they are dying so they can interact and communicate with each

# **connecting** development to life

## Effective Strategies for Communicating with a Dying Person

Effective strategies for communicating with a dying person include the following suggestions:

- Establish your presence, be at the same eye level; don't be afraid to touch the dying person—dying individuals are often starved for human touch.
- Eliminate distraction—for example, ask if it is okay to turn off the TV. Realize that excessive small talk can be a distraction.
- Dying individuals who are very frail often have little energy. If the dying person you are visiting is very frail, you may not want to visit for very long.
- Don't insist that the dying person feel acceptance about death if the dying person wants to deny the reality of the situation; on the other hand, don't insist on denial if the dying individual indicates acceptance.
- Allow the dying person to express guilt or anger; encourage the expression of feelings.
- Don't be afraid to ask the person what the expected outcome for the illness is. Discuss alternatives and unfinished business.
- Sometimes dying individuals don't have access to other people. Ask the dying person if there is anyone he or she would like to see that you can contact.
- Encourage the dying individual to reminisce, especially if you have memories in common.

What are some good strategies for communicating with a dying person?  
©Stockbroker/Photolibrary

- Talk with the individual when she or he wishes to talk. If this is impossible, make an appointment and keep it.
- Express your regard for the dying individual. Don't be afraid to express love, and don't be afraid to say good-bye.

other on the basis of this mutual knowledge (Banja, 2005). What are some of the advantages of this open awareness for the dying individual? First, dying individuals can close their lives in accord with their own ideas about proper dying. Second, they may be able to complete some plans and projects, to make arrangements for survivors, and to participate in decisions about a funeral and burial. Third, dying individuals have the opportunity to reminisce and to converse with people who have been important to them. And fourth, individuals who know they are dying have more understanding of what is happening within their bodies and what the medical staff is doing for them (Kalish, 1981).

In addition to keeping communication open, some experts reason that conversation should not focus on mental pathology or preparation for death but should focus on strengths of the individual and preparation for the remainder of life. Since external accomplishments are not possible, communication should be directed toward internal growth. Keep in mind also that important support for a dying individual may come not only from mental health professionals but also from nurses, physicians, a spouse, or intimate friends. In *Connecting Development to Life*, you can read further about effective ways to communicate with a dying person.

## GRIEVING

Our exploration of grief focuses on dimensions of grieving, the dual-process model of coping with bereavement, and cultural diversity in healthy grieving.

**Dimensions of Grieving** Grief is the emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love. Grief is not a simple emotional state but rather a complex, evolving process with multiple dimensions (Bui & Okereke, 2018; Lichtenberg, 2017; Sheperd, 2018; Waller & others, 2016). In this view, pining

**grief** The emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love.

**Everyone can master grief  
but he who has it.**

—WILLIAM SHAKESPEARE  
*English Playwright, 17th Century*

for the lost person is one important dimension. Pining or yearning reflects an intermittent, recurrent wish or need to recover the lost person. Another important dimension of grief is separation anxiety, which not only includes pining and preoccupation with thoughts of the deceased person but also focuses on places and things associated with the deceased, as well as crying or sighing (Root & Exline, 2014; Sirrine, Salloum, & Boothroyd, 2017). Grief may also involve despair and sadness, which include a sense of hopelessness and defeat, depressive symptoms, apathy, loss of meaning for activities that used to involve the person who is gone, and growing desolation (Milic & others, 2017; Schwartz, Howell, & Jamison, 2018). One study found that older adults who were bereaved had more dysregulated cortisol patterns, indicative of the intensity of their stress (Holland & others, 2014). And another study found that college students who had lost someone close to them in campus shootings and had severe posttraumatic stress symptoms four months after the shootings were more likely to have severe grief one year after the shootings (Smith & others, 2015).

The feelings involved in grief occur repeatedly shortly after a loss (Shear, 2012a, b). As time passes, pining and protest over the loss tend to diminish, although episodes of depression and apathy may remain or increase. The sense of separation anxiety and loss may continue to the end of one's life, but most of us emerge from grief's tears, turning our attention once again to productive tasks and regaining a more positive view of life (Mendes, 2016).

The grieving process is more like a roller-coaster ride than an orderly progression of stages with clear-cut time frames. The ups and downs of grief often involve rapidly changing emotions, meeting the challenges of learning new skills, detecting personal weaknesses and limitations, creating new patterns of behavior, and forming new friendships and relationships (Feldon, 2003). For most individuals, grief becomes more manageable over time, with fewer abrupt highs and lows. But many grieving spouses report that even though time has brought some healing, they have never gotten over their loss. They have just learned to live with it. One study found that individuals in the early stages of spousal bereavement are at increased risk for distress in situations with special significance for the couple, such as the late spouse's birthday or a wedding anniversary (Carr & others, 2014).

Long-term grief is sometimes masked and can predispose individuals to become depressed and even suicidal (Miller, 2012). Good family communication can help reduce the incidence of depression and suicidal thoughts. An estimated 80 to 90 percent of survivors experience normal or uncomplicated grief reactions that include sadness and even disbelief or considerable anguish. By six months after their loss, they accept it as a reality, are more optimistic about the future, and function competently in their everyday lives.

However, even six months after their loss, some individuals have difficulty moving on with their lives and continue feeling numb or detached, believing their life is empty without the deceased, and feeling that the future has no meaning. This type of grief reaction has been referred to as *prolonged or complicated grief* (Glickman, Shear, & Wall, 2016; Holland & others, 2016; Li, Tendeiro, & Stroebe, 2018; Tsai & others, 2018). It is estimated that approximately 7 to 10 percent of bereaved individuals have this type of grief (MacCallum & Bryant, 2013; Shear, Ghesquiere, & Glickman, 2013). Prolonged grief, in which feelings of despair remain unresolved over an extended period of time, is described as *complicated grief* or **prolonged grief disorder** (Maciejewski & Prigerson, 2017; Prigerson & Maciejewski, 2014). Prolonged grief usually has negative consequences for physical and mental health (Djelantik & others, 2017; Tang & Chow, 2017; Trevino & others, 2018). A person who loses someone on whom he or she was emotionally dependent is often at greatest risk for developing prolonged grief (Rodriquez Villar & others, 2012). Also, a recent 7-year longitudinal study of older adults found that those who were experiencing prolonged grief had greater cognitive decline than their counterparts with normal grief (Perez & others, 2018). And another recent study revealed that individuals with complicated grief had a higher level of the personality trait neuroticism (Goetter & others, 2018).

Complicated grief or prolonged grief disorder was considered for possible inclusion in DSM-V, the psychiatric classification system for mental health disorders (Bryant, 2012, 2013). Although it ended up not being included as a psychiatric disorder, it was described in an Appendix (American Psychiatric Association, 2013). The argument for not including complicated grief or prolonged grief as a psychiatric disorder was based on concerns that normal grieving would be viewed as a medical condition (Breen & others, 2015).

Recently, there has been a substantial amount of research on complicated or prolonged grief (Breen & others, 2018; Heeke & others, 2017; Li & Prigerson, 2016; Nam, 2016; Nielsen &

**prolonged grief disorder** Grief that involves enduring despair and remains unresolved over an extended period of time.

others, 2017; Trevino & others, 2018; Wilson & others, 2017). Following are studies that provide information about various aspects of complicated or prolonged grief disorder:

- In a recent meta-analysis, 9.8 percent of adult bereavement cases were classified as characterized by prolonged grief disorder (Lundorff & others, 2017). In this study, the older individuals were, the more likely prolonged grief disorder was present.
- Prolonged grief was more likely to occur when individuals had lost their spouse, lost a loved one unexpectedly, or spent time with the deceased every day in the last week of the person's life (Fujisawa & others, 2010).
- Adults with depression were more likely to also have complicated grief (Sung & others, 2011).
- Complicated grief was more likely to be present in older adults when the grief was in response to the death of a child or a spouse (Newsom & others, 2011).
- Among individuals diagnosed with complicated grief, 40 percent reported at least one full or limited-symptom grief-related panic attack in the past week (Bui & others, 2015).
- Cognitive-behavior therapy reduced prolonged grief symptoms (Bartl & others, 2018).

Another type of grief is *disenfranchised grief*, which describes an individual's grief over a deceased person that is a socially ambiguous loss and can't be openly mourned or supported (Patlamazoglou, Simmonds, & Snell, 2018; Tullis, 2017; Yu & others, 2016). Examples of disenfranchised grief include a relationship that isn't socially recognized such as an ex-spouse, a hidden loss such as an abortion, and circumstances of the death that are stigmatized such as death because of AIDS. Disenfranchised grief may intensify an individual's grief because the feelings cannot be publicly acknowledged. This type of grief may be hidden or repressed for many years, only to be reawakened by later deaths.

A death can sometimes bring out the best in people as they provide support and caring for the grieving person, but in other cases a death can bring out the worst in people (Lightner & Hathaway, 1990). When death brings out the best, mourners feel recognized and consoled, touched by others' sympathy, and shored up by their kindness. Consider Jennifer Block's experience. After her husband died, her best friend encouraged her to get out and do things. The friend called Jennifer every day and took her out for ice cream, on walks, and to community events. Jennifer says that she will never forget her friend's support and caring.

Sometimes, however, friends may say and do the wrong things when someone dies (Lightner & Hathaway, 1990). Their grieving friend may feel slighted, insulted, disappointed, and alone when this happens. Perhaps a friend disappears from sight or makes an inappropriate or cruel remark, such as "I thought you two were not getting along that well anyway." Consider Martha Cooper's experience. When her husband died, her friend told her to forget that part of her life because it was over. Martha was terribly disappointed at her friend's lack of empathy. As Martha remarked, you can't just forget about someone who was a part of your life for 45 years.

**Dual-Process Model of Coping with Bereavement** The **dual-process model** of coping with bereavement has two main dimensions: (1) loss-oriented stressors, and (2) restoration-oriented stressors (Stroebe & others, 2017a, b; Stroebe & Schut, 2015, 2017). Loss-oriented stressors focus on the deceased individual and can include grief work and both positive and negative reappraisals of the loss. A positive reappraisal of the loss might include acknowledging that death brought relief at the end of suffering, whereas a negative reappraisal might involve yearning for the loved one and ruminating about the death. Restoration-oriented stressors involve the secondary stressors that emerge as indirect outcomes of bereavement (Caserta & others, 2014; Mulligan & Karel, 2018). They can include a changing identity (such as from "wife" to "widow") and mastering skills (such as dealing with finances). Restoration rebuilds "shattered assumptions about the world and one's own place in it."

In the dual-process model, effective coping with bereavement often involves an oscillation between coping with loss and coping with restoration (Albuquerque & others, 2017; Cantwell-Bartl, 2018; Chen & others, 2018; Stroebe & others, 2017a, b). Earlier models often emphasized a sequence of coping with loss through such strategies as grief work as an initial phase, followed by restoration efforts. However, in the dual-process model, coping with loss and engaging in restoration can be carried out concurrently (Richardson, 2007). According to this model, the person coping with death might be involved in grief group therapy while settling the affairs of

**dual-process model** A model of coping with bereavement that emphasizes oscillation between two dimensions: (1) loss-oriented stressors, and (2) restoration-oriented stressors.

the loved one. Oscillation might occur in the short term during a particular day as well as across weeks, months, and even years. Although loss and restoration coping can occur concurrently, over time there often is an initial emphasis on coping with loss followed by greater emphasis on restoration (Milberg & others, 2008).

Recently, a variation of the dual-process model has been developed for families (Stroebe & Schut, 2015, 2017; Stroebe & others, 2017a, b). The original model focused mainly on the bereaved individual but many people do not grieve in isolation; most do so with immediate family members and relatives who also are bereaved by the loss. This recent extension of the dual-process model also focuses on such matters as reduced finances, legal consequences, and changed family relationships that have to be dealt with, and seeks to integrate intrapersonal and interpersonal coping.

**Coping and Type of Death** The impact of death on surviving individuals is strongly influenced by the circumstances under which the death occurred (Lovgren & others, 2018; Tobin, Lambert, & McCarthy, 2018). Deaths that are sudden, untimely, violent, or traumatic

are likely to have more intense and prolonged effects on surviving individuals and make the coping process more difficult for them (Creighton & others, 2018; Feigelman & others, 2018; Pitman & others, 2018). Such deaths often are accompanied by post-traumatic stress disorder (PTSD) symptoms, such as intrusive thoughts, flashbacks, nightmares, sleep disturbance, problems in concentrating, and other difficulties (Nakajima & others, 2012). The death of a child can be especially devastating and extremely difficult for parents to cope with (Eskola & others, 2017; Fu & others, 2018; Keim & others, 2017; Stevenson & others, 2017).

**Cultural Diversity in Healthy Grieving** Some approaches to grieving emphasize the importance of breaking bonds with the deceased and returning to autonomous lifestyles. People who persist in holding on to the deceased are believed to be in need of therapy. However, some doubt has been cast on whether this recommendation to break bonds is always the best therapeutic advice (Reisman, 2001).

Analyses of non-Western cultures suggest that beliefs about maintaining bonds with the deceased vary extensively. Maintenance of ties with the deceased is accepted and sustained in the religious rituals of Japan. Among the Hopi of Arizona, the deceased are forgotten as quickly as possible and life is carried on as usual. Their funeral ritual concludes with a break-off between mortals and spirits. The diversity of grieving is nowhere more clear than in two Muslim societies—one in Egypt, the other in Bali. In Egypt, the bereaved are encouraged to dwell at length on their grief, surrounded by others who relate similarly tragic accounts and express their own sorrow. By contrast, in Bali, the bereaved are encouraged to laugh and be joyful.

In sum, people grieve in a variety of ways (Bui & Okereke, 2018; Chen & others, 2018). The diverse grieving patterns are culturally embedded practices. Thus, there is no one right, ideal way to grieve. There are many different ways to feel about a deceased person and no set series of stages that the bereaved must pass through to become well adjusted. The stoic widower may need to cry out over his loss at times. The weeping widow may need to put her husband's wishes aside as she becomes the financial manager of her estate. What is needed is an understanding that healthy coping with the death of a loved one involves growth, flexibility, and appropriateness within a cultural context.

## MAKING SENSE OF THE WORLD

Not only do many individuals who face death search for meaning in life, so do many bereaved individuals (Breen & others, 2018; Park, 2016; Steffen & Coyle, 2017). One beneficial aspect of grieving is that it can stimulate people to try to make sense of their world (Bianco, Sambin, & Palmieri, 2017; Kalanithi, 2016). A common occurrence is to go over again and again all of the events that led up to the death. In the days and weeks after the death, the closest family members share experiences with each other, sometimes reminiscing over family experiences. In one study, women who became widowed in midlife were challenged by the crisis of their husband's death to examine meaningful directions for their lives (Danforth & Glass, 2001). Another study

How might grieving vary across individuals and cultures?

©Xinhua/eyevine/Redux

found that mourners who expressed positive themes of hope showed better adjustment than those who focused on negative themes of pain and suffering (Gamino & Sewell, 2004). And one study revealed that finding meaning in the death of a spouse was linked to a lower level of anger during bereavement (Kim, 2009). In a recent study, meaning-making following a child's death was examined (Meert & others, 2015). From 8 to 20 weeks following the child's death, the child's intensive care physician conducted a bereavement meeting with 53 parents of 35 children who had died. Four meaning-making processes were identified in the meetings: (1) sense making (seeking biomedical explanations for the death, revisiting parents' prior decisions and roles, and assigning blame); (2) benefit finding (exploring possible positive consequences of the death, such as ways to help others; providing feedback to the hospital; and making donations); (3) continuing bonds (reminiscing about the child, sharing photographs, and participating in community events to honor the child); and (4) identity reconstruction (changes in the parents' sense of self, including changes in relationships, work, and home).

When a death is caused by an accident or a disaster, the effort to make sense of it is pursued more vigorously (Park, 2016). As added pieces of news come trickling in, they are integrated into the puzzle. The bereaved want to put the death into a perspective that they can understand—divine intervention, a curse from a neighboring tribe, a logical sequence of cause and effect, or whatever it may be. A study of more than 1,000 college students found that making sense was an important factor in their grieving of a violent loss by accident, homicide, or suicide (Currier, Holland, & Neimeyer, 2006).

## LOSING A LIFE PARTNER

In 2015 in the United States, 14 percent of 65- to 74-year-olds, 31 percent of 75- to 84-year-olds, and 59 percent of those 85 and over were widowed (Administration on Aging, 2015). Approximately three times as many women as men are widowed. Those left behind after the death of an intimate partner often suffer profound grief, die earlier, and may endure financial loss, loneliness, increased physical illness, and psychological disorders, including depression (Daoulah & others, 2017; Siflinger, 2017). Consider the following studies that reflect such outcomes:

- In a recent cross-cultural study in the United States, England, Europe, Korea, and China, depression peaked in the first year of widowhood for men and women (Jadhav & Weir, 2017). In this study, women recovered to levels compared to married individuals in all countries, but widowed men continued to have high levels of depression 6 to 10 years post-widowed everywhere except in Europe.
- Becoming widowed was associated with a 48 percent increase in earlier death (Sullivan & Fenelon, 2014).
- Mexican American older adults experienced a significant increase in depressive symptoms during the transition to widowhood (Monserud & Markides, 2017). In this study, frequent church attendance was a protective factor against increases in depressive symptoms.
- Widowed individuals who reported having higher marital quality subsequently had more depressive symptoms after their spouse died (Schaan, 2013).
- Volunteering reduced widowed older adults' loneliness (Carr & others, 2018)

Becoming widowed is likely to be especially difficult when individuals have been happily married for a number of decades. In such circumstances, losing your spouse, who may also be your best friend and with whom you have lived a deeply connected life, can be extremely upsetting and difficult to cope with.

Surviving spouses seek to cope with the loss of their spouse in various ways (Bennett & others, 2018; Collins, 2018; Hasmanova, 2016; Park, 2016). In one study, widowed individuals were more likely to intensify their religious and spiritual beliefs following the death of a spouse, and this increase was linked with a lower level of grief (Brown & others, 2004). Another study revealed that finding meaning in the death of a spouse was linked to a lower level of anger during bereavement (Kim, 2009). And researchers have found that widowed persons who did

These restaurant workers, who lost their jobs on 9/11/01, have made a bittersweet return by establishing a New York restaurant they call their own. Colors, named for the many nationalities and ethnic groups among its owners, is believed to be the city's first cooperative restaurant. World-famous restaurant Windows on the World was destroyed and 73 workers killed when the Twin Towers were destroyed by terrorists. The former Windows survivors at the new venture planned to split 60 percent of the profits between themselves and to donate the rest to a fund to open other cooperative restaurants.

not expect to be reunited with their loved ones in the afterlife reported more depression, anger, and intrusive thoughts at 6 and 18 months after their loss (Carr & Sharp, 2014). The poorer and less educated they are, the lonelier they tend to be. The bereaved are also at increased risk for many health problems (Jadhav & Weir, 2017).

Optimal adjustment after a death depends on several factors (Reksiedler & others, 2018). For example, researchers have found that religiosity and coping skills are related to well-being following the loss of a spouse in late adulthood (Jones & others, 2018; Kristiansen & others, 2016).

Also, for both widows and widowers, social support helps them adjust to the death of a spouse (Dahlberg, Agahi, & Lennartsson, 2018; Hendrickson & others, 2018; Huang & others, 2017; Shankar & others, 2017). The Widow-to-Widow program, begun in the 1960s, provides support for newly widowed women. Volunteer widows reach out to other widows, introducing them to others who may have similar problems, leading group discussions, and organizing social activities. The program has been adopted by the AARP and disseminated throughout the United States as the Widowed Persons Service. The model has since been adopted by numerous community organizations to provide support for those going through a difficult transition. Other widow support groups also are often beneficial in reducing depression in bereaved spouses (Collins, 2018; Reksiedler & others, 2018).

## FORMS OF MOURNING

One decision facing the bereaved is what to do with the body. In the United States, in 2016, 50.1 percent of deaths were followed by cremation—a significant increase from a cremation rate of 14 percent in 1985 and 27 percent in 2000 (Cremation Association of North America, 2017). In 2016, in Canada 70.2 percent of deaths were followed by cremation. Projections indicate that in 2020, 56.3 percent of U.S. deaths will be followed by cremation while Canada will increase to 79.8 percent. Cremation is more popular in the Pacific region of the United States, less popular in the South. Cremation also is more popular in Canada than in the United States and most popular of all in Japan and many other Asian countries.

The funeral is an important aspect of mourning in many cultures. In the United States, the trend is away from public funerals and displaying the dead body in an open casket and toward private funerals followed by a memorial ceremony (Beard & Burger, 2017, 2018).

The funeral industry in the United States has been a focus of controversy in recent years (Beard & Burger, 2017, 2018). Funeral directors and their supporters argue that the funeral provides a form of closure to the relationship with the deceased, especially when there is an open casket. Their critics claim that funeral directors are just trying to make money and that embalming is grotesque. One way to avoid being exploited during bereavement is to purchase funeral arrangements in advance, but many people are reluctant to do this.

(Left) ©Russell Underwood/Corbis/Getty Images; (right) ©Paul Almasy/Corbis/VCG/Getty Images

In some cultures, a ceremonial meal is shared after a death; in others, a black armband is worn by bereaved family members for one year following a death. Cultures vary in how they practice mourning. Two of those cultures are the Amish and traditional Judaism (Worthington, 1989).

The Amish are a conservative Christian group with approximately 80,000 members in the United States, Ontario, and several small settlements in South and Central America. The Amish live in a family-oriented society in which family and community support are essential for survival. Today, they live at the same unhurried pace as that of their ancestors, using horses instead of cars and facing death with the same steadfast faith as their forebears. At the time of death, close neighbors assume the responsibility of notifying others of the death. The Amish community handles virtually all aspects of the funeral.

The funeral service is held in a barn in the warmer months and in a house during colder months. Calm acceptance of death, influenced by a deep religious faith, is an integral part of the Amish culture. Following the funeral, a high level of support is given to the bereaved family for at least a year. Visits to the family, special scrapbooks and handmade items for family members, new work projects started for the widow, and quilting days that combine fellowship and productivity are among the supports given to the bereaved family. A profound example of the Amish culture's religious faith and acceptance of death occurred after Charles Roberts shot and killed five Amish schoolgirls and then apparently took his own life in October 2006 in Bart Township, Pennsylvania. Soon after the murders and suicide, members of the Amish community visited his widow and offered their support and forgiveness.

The family and community also have specific and important roles in mourning in traditional Judaism. The program of mourning is divided into graduated time periods, each with its appropriate practices. The observance of these practices is required of the spouse and the immediate blood relatives of the deceased. The first period is *aninut*, the period between death and burial. The next two periods make up *avelut*, or mourning proper. The first of these is *shivah*, a period of seven days, which commences with the burial. It is followed by *sheloshim*, the 30-day period following the burial, including shivah. At the end of *sheloshim*, the mourning process is considered over for all but one's parents. For parents, mourning continues for 11 months, although observances are minimal.

The seven-day period of the *shivah* is especially important in traditional Judaism. The mourners, sitting together as a group through an extended period, have an opportunity to project their feelings to the group as a whole. Visits from others during *shivah* may help the mourners deal with feelings of guilt. After *shivah*, the mourners are encouraged to resume normal social interaction. In fact, it is customary for the mourners to walk together a short distance as a symbol of their return to society. In its entirety, the elaborate mourning system of traditional Judaism is designed to promote personal growth and to reintegrate bereaved individuals into the community.

### Death, Dying, and Grieving

#### 1 The Death System and Cultural Contexts

The Death System and Its Cultural Variations

Changing Historical Circumstances

**LG1** Describe the death system and its cultural and historical contexts.

- In Kastenbaum's view, every culture has a death system that involves these components: people, places, times, objects, and symbols. Most cultures do not view death as the end of existence—spiritual life is thought to continue. Most societies throughout history have had philosophical or religious beliefs about death, and most societies have rituals that deal with death. The United States has been described as more of a death-denying and death-avoiding culture than most cultures.
- When, where, and why people die have changed historically. Today, death occurs most often among older adults. More than 80 percent of all deaths in the United States now occur in a hospital or other institution; our exposure to death in the family has been minimized.

#### 2 Defining Death and Life/Death Issues

Issues in Determining Death

Decisions Regarding Life, Death, and Health Care

**LG2** Evaluate issues in determining death and decisions regarding death.

- Twenty-five years ago, determining whether someone was dead was simpler than it is today. Brain death is a neurological definition of death which states that a person is brain dead when all electrical activity of the brain has ceased for a specified period of time. Medical experts debate whether this cessation should include the higher and lower brain functions or just the higher cortical functions. Currently, most physicians define brain death as the death of both the higher cortical functions and the lower brain stem functions.
- Decisions regarding life, death, and health care can involve creating a living will, considering the possibility of euthanasia, and arranging for hospice care. Living wills and advance directives are increasingly used.
- Euthanasia (“mercy killing”) is the act of painlessly ending the life of a person who is suffering from an incurable disease or disability. Distinctions are made between active and passive euthanasia. Assisted suicide involves the patient self-administering the lethal medication. Hospice care emphasizes reducing pain and suffering rather than prolonging life.

### 3 A Developmental Perspective on Death

Causes of Death

Attitudes Toward Death at Different Points in the Life Span

LG3

Discuss death and attitudes about it at different points in development.

- Although death is more likely to occur in late adulthood, death can come at any point in development. In children and younger adults, death is more likely to occur because of accidents or illness; in older adults, death is more likely to occur because of chronic illnesses such as heart disease or cancer.
- Infants do not have a concept of death. Preschool children also have little concept of death. Preschool children sometimes blame themselves for a person's death.
- In the elementary school years, children develop a more realistic orientation toward death. Most psychologists argue that honesty is the best strategy for helping children cope with death.
- Death may be glossed over in adolescence. Adolescents have more abstract, philosophical views of death than children do.
- There is no evidence that a special orientation toward death emerges in early adulthood. Middle adulthood is a time when adults show a heightened consciousness about death and death anxiety. Older adults often show less death anxiety than middle-aged adults, but older adults experience and converse about death more. Attitudes about death may vary considerably among adults of any age.

### 4 Facing One's Own Death

Kübler-Ross' Stages of Dying

Perceived Control and Denial

The Contexts in Which People Die

LG4

Explain the psychological aspects involved in facing one's own death and the contexts in which people die.

- Kübler-Ross proposed five stages of dying: denial and isolation, anger, bargaining, depression, and acceptance. Not all individuals go through the same sequence.
- Perceived control and denial may work together as an adaptive orientation for the dying individual. Denial can be adaptive or maladaptive, depending on the circumstances.
- The fact that most deaths in the United States occur in hospitals has advantages and disadvantages. Most individuals say they would rather die at home, but they are concerned that they will be a burden to family members and they worry about the lack of medical care at home.

### 5 Coping with the Death of Someone Else

Communicating with a Dying Person

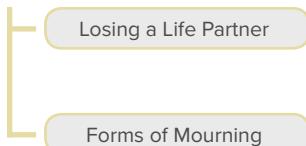

Grieving

Making Sense of the World

LG5

Identify ways to cope with the death of another person.

- Most psychologists recommend open communication with the dying. Communication should not dwell on mental pathology or preparation for death but should emphasize the dying person's strengths.
- Grief is the emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love. Grief is multidimensional and in some cases may last for years. Prolonged grief involves enduring despair that is still unresolved after an extended period of time.
- In the dual-process model of coping with bereavement, oscillation occurs between two dimensions: (1) loss-oriented stressors and (2) restoration-oriented stressors. Grief and coping vary with the type of death. There are cultural variations in grieving.
- The grieving process may stimulate individuals to strive to make sense of their world. When a death is caused by an accident or disaster, the effort to make sense of it is pursued more vigorously.

- The death of an intimate partner often leads to profound grief. The bereaved are at risk for many health problems, although there are variations in the distress experienced by a surviving spouse. Social support benefits widows and widowers.
- Forms of mourning vary across cultures. Approximately two-thirds of corpses are disposed of by burial, one-third by cremation. An important aspect of mourning in many cultures is the funeral. In recent years, the funeral industry has been the focus of controversy. In some cultures, a ceremonial meal is shared by mourners after a death.

## key terms

acceptance  
active euthanasia  
anger  
assisted suicide

bargaining  
brain death  
denial and isolation  
depression

dual-process model  
euthanasia  
grief  
hospice

palliative care  
passive euthanasia  
prolonged grief disorder

Elisabeth Kübler-Ross

# glossary

## A

**A-not-B error** Error that occurs when infants make the mistake of selecting the familiar hiding place (A) rather than the new hiding place (B) of an object.

**acceptance** Kübler-Ross' fifth stage of dying, in which the dying person develops a sense of peace, an acceptance of her or his fate, and, in many cases, a desire to be left alone.

**accommodation** Piagetian concept of adjusting schemes to fit new information and experiences.

**active (niche-picking) genotype-environment correlations** Correlations that exist when children seek out environments they find compatible and stimulating.

**active euthanasia** Death induced deliberately, as by injecting a lethal dose of a drug.

**activity theory** The theory that the more active and involved older adults are, the more likely they are to be satisfied with their lives.

**addiction** A pattern of behavior characterized by an overwhelming involvement with using a drug and a preoccupation with securing its supply.

**adolescent egocentrism** The heightened self-consciousness of adolescents.

**adoption study** A study in which investigators seek to discover whether, in behavior and psychological characteristics, adopted children are more like their adoptive parents, who provided a home environment, or more like their biological parents, who contributed their heredity. Another form of the adoption study compares adoptive and biological siblings.

**aerobic exercise** Sustained exercise (such as jogging, swimming, or cycling) that stimulates heart and lung activity.

**affectionate love** In this type of love, also called companionate love, an individual desires to have the other person near and has a deep, caring affection for the other person.

**affordances** Opportunities for interaction offered by objects that fit within our capabilities to perform functional activities.

**afterbirth** The third stage of birth, when the placenta, umbilical cord, and other membranes are detached and expelled.

**ageism** Prejudice against others because of their age, especially prejudice against older adults.

**Alzheimer disease** A progressive, irreversible brain disorder characterized by a gradual deterioration of memory, reasoning, language, and eventually, physical function.

**amnion** The part of the prenatal life-support system that consists of a sac containing a clear fluid in which the developing embryo floats.

**amygdala** The region of the brain that is the seat of emotions.

**androgyny** The presence of positive masculine and feminine characteristics in the same person.

**anger** Kübler-Ross' second stage of dying, in which the dying person's denial gives way to anger, resentment, rage, and envy.

**anger cry** A variation of the basic cry, with more excess air forced through the vocal cords.

**animism** The belief that inanimate objects have lifelike qualities and are capable of action.

**anorexia nervosa** An eating disorder that involves the relentless pursuit of thinness through starvation.

**anxious attachment style** An attachment style that describes adults who demand closeness, are less trusting, and are more emotional, jealous, and possessive.

**Apgar Scale** A widely used method of assessing the health of newborns at one and five minutes after birth. The Apgar Scale evaluates an infant's heart rate, respiratory effort, muscle tone, body color, and reflex irritability.

**aphasia** A loss or impairment of language ability caused by brain damage.

**arthritis** Inflammation of the joints accompanied by pain, stiffness, and movement problems; this disease is especially common in older adults.

**Asperger syndrome** A relatively mild autism spectrum disorder in which the child has relatively good verbal language skills, milder nonverbal language problems, and a restricted range of interests and relationships.

**assimilation** Piagetian concept of using existing schemes to deal with new information or experiences.

**assisted suicide** Requires the patient to self-administer the lethal medication, and the patient is allowed to decide when and where to do this.

**attachment** A close emotional bond between two people.

**attention** The focusing of mental resources on select information.

**attention deficit hyperactivity disorder (ADHD)**

A disability in which children consistently show one or more of the following characteristics: (1) inattention, (2) hyperactivity, and (3) impulsivity.

**authoritarian parenting** A restrictive, punitive style in which parents exhort the child to follow their directions and to respect their work and effort. The authoritarian parent places firm limits and controls on the child and allows little verbal exchange. Authoritarian parenting is associated with children's social incompetence.

**authoritative parenting** A parenting style in which parents encourage their children to be

independent but still place limits and controls on their actions. Extensive verbal give-and-take is allowed, and parents are warm and nurturing toward the child. Authoritative parenting is associated with children's social competence.

**autism spectrum disorders (ASD)** Also called pervasive developmental disorders, they range from the severe disorder labeled autistic disorder to the milder disorder called Asperger syndrome. Children with these disorders are characterized by problems in social interaction, verbal and nonverbal communication, and repetitive behaviors.

**autistic disorder** A severe autism spectrum disorder that has its onset in the first three years of life and includes deficiencies in social relationships, abnormalities in communication, and restricted, repetitive, and stereotyped patterns of behavior.

**autonomous morality** In Piaget's theory, older children (about 10 years of age and older) become aware that rules and laws are created by people and that in judging an action one should consider the actor's intentions as well as the consequences.

**average children** Children who receive an average number of both positive and negative nominations from peers.

**avoidant attachment style** An attachment style that describes adults who are hesitant about getting involved in romantic relationships and once in a relationship tend to distance themselves from their partner.

## B

**bargaining** Kübler-Ross' third stage of dying, in which the dying person develops the hope that death can somehow be postponed.

**basic cry** A rhythmic pattern usually consisting of a cry, a briefer silence, a shorter inspiratory whistle that is higher pitched than the main cry, and then a brief rest before the next cry.

**Bayley Scales of Infant Development**

Scales developed by Nancy Bayley that are widely used to assess infant development. The current version has three components: a mental scale, a motor scale, and an infant behavior profile.

**behavior genetics** The field that seeks to discover the influence of heredity and environment on individual differences in human traits and development.

**Big Five factors of personality** Emotional stability (neuroticism), extraversion, openness to experience, agreeableness, and conscientiousness.

**binge eating disorder (BED)** Involves frequent binge eating but without compensatory behavior like the purging that characterizes bulimics.

**biological processes** Changes in an individual's physical nature.

**blastocyst** The inner layer of cells that develops during the germinal period. These cells later develop into the embryo.

**bonding** The formation of a close connection, especially a physical bond, between parents and their newborn in the period shortly after birth.

**brain death** A neurological definition of death. A person is brain dead when all electrical activity of the brain has ceased for a specified period of time. A flat EEG recording is one criterion of brain death.

**brainstorming** A technique in which individuals are encouraged to come up with creative ideas in a group, play off each other's ideas, and say almost anything that comes to mind.

#### Brazelton Neonatal Behavioral Assessment

**Scale (NBAS)** A measure that is used in the first month of life to assess the newborn's neurological development, reflexes, and reactions to people and objects.

**breech position** The baby's position in the uterus that causes the buttocks to be the first part to emerge from the vagina.

**Broca's area** An area in the brain's left frontal lobe that is involved in speech production.

#### Bronfenbrenner's ecological theory

Bronfenbrenner's environmental systems theory that focuses on five environmental systems: microsystem, mesosystem, exosystem, macrosystem, and chronosystem.

**bulimia nervosa** An eating disorder in which the individual consistently follows a binge-and-purge pattern.

## C

**care perspective** The moral perspective of Carol Gilligan, which views people in terms of their connectedness with others and emphasizes interpersonal communication, relationships with others, and concern for others.

**case study** An in-depth look at a single individual.

**cataracts** A thickening of the lens of the eye that causes vision to become cloudy, opaque, and distorted.

**cellular clock theory** Leonard Hayflick's theory that the maximum number of times that human cells can divide is about 75 to 80. As we age, our cells have less capacity to divide.

**centration** Focusing attention on one characteristic to the exclusion of all others.

**cephalocaudal pattern** Developmental sequence in which the earliest growth always occurs at the top—the head—with physical growth in size, weight, and feature differentiation gradually working from top to bottom.

**cesarean delivery** Surgical procedure in which the baby is removed from the mother's uterus through an incision made in her abdomen.

**child-centered kindergarten** Education that involves the whole child by considering both the child's physical, cognitive, and socioemotional development and the child's needs, interests, and learning styles.

**child-directed speech** Language spoken in a higher pitch and slower speed than normal, with simple words and sentences.

**chromosomes** Threadlike structures that come in 23 pairs, with one member of each pair coming from each parent. Chromosomes contain the genetic substance DNA.

**chronic disorders** Disorders that are characterized by slow onset and long duration. They are rare in early adulthood, increase during middle adulthood, and become common in late adulthood.

**climacteric** The midlife transition during which fertility declines.

**clique** A small group of about five or six individuals that may form among adolescents who engage in similar activities.

**cognitive control** Effective control of thinking in a number of areas, including controlling attention, reducing interfering thoughts, and being cognitively flexible.

**cognitive mechanics** The "hardware" of the mind, reflecting the neurophysiological architecture of the brain. Cognitive mechanics involve the speed and accuracy of the processes involving sensory input, visual and motor memory, discrimination, comparison, and categorization.

**cognitive pragmatics** The culture-based "software programs" of the mind. Cognitive pragmatics include reading and writing skills, language comprehension, educational qualifications, professional skills, and also knowledge about the self and life skills that help us to master or cope with life.

**cognitive processes** Changes in an individual's thought, intelligence, and language.

**cohort effects** Characteristics determined by a person's time of birth, era, or generation rather than the person's actual age.

**commitment** Marcia's term for the part of identity development in which adolescents show a personal investment in identity.

**concepts** Cognitive groupings of similar objects, events, people, or ideas.

**conscience** An internal regulation of standards of right and wrong that involves integrating moral thought, feeling, and behavior.

**consensual validation** An explanation of why individuals are attracted to people who are similar to them. Our own attitudes and behavior are supported and validated when someone else's attitudes and behavior are similar to our own.

**conservation** In Piaget's theory, awareness that altering an object's or a substance's appearance does not change its basic properties.

**constructive play** Play that combines sensorimotor and repetitive activity with symbolic representation of ideas. Constructive play occurs when children engage in self-regulated creation or construction of a product or a solution.

**constructivist approach** A learner-centered educational approach that emphasizes the importance of individuals actively constructing their knowledge and understanding with guidance from the teacher.

**contemporary life-events approach** Approach emphasizing that how a life event influences the individual's development depends not only on the life event but also on mediating factors, the individual's adaptation to the life event, the life-stage context, and the sociohistorical context.

**continuity-discontinuity issue** Debate about the extent to which development involves gradual, cumulative change (continuity) or distinct stages (discontinuity).

**controversial children** Children who are frequently nominated both as a best friend and as being disliked by their peers.

**conventional reasoning** The second, or intermediate, level in Kohlberg's theory of moral development. At this level, individuals abide by certain standards, but these are standards set by others such as parents or society.

**convergent thinking** Thinking that produces one correct answer and is characteristic of the kind of thinking tested by standardized intelligence tests.

**convoy model of social relations** Model in which individuals go through life embedded in a personal network of individuals to whom they give and from whom they receive support.

**coordination of secondary circular reactions** Piaget's fourth sensorimotor substage, which develops between 8 and 12 months of age. Actions become more outwardly directed, and infants coordinate schemes and act with intentionality.

**coparenting** Support parents provide for each other in jointly raising their children.

**core knowledge approach** Theory that infants are born with domain-specific innate knowledge systems.

**corpus callosum** The location where fibers connect the brain's left and right hemispheres.

**correlation coefficient** A number based on statistical analysis that is used to describe the degree of association between two variables.

**correlational research** Research that attempts to determine the strength of the relationship between two or more events or characteristics.

**creative thinking** The ability to think in novel and unusual ways and to come up with unique solutions to problems.

**crisis** Marcia's term for a period of identity development during which the adolescent is exploring alternatives.

**critical thinking** Thinking reflectively and productively, as well as evaluating evidence.

**cross-cultural studies** Comparison of one culture with one or more other cultures. These provide information about the degree to which development is similar, or universal, across cultures, and the degree to which it is culture-specific.

**cross-sectional approach** A research strategy in which individuals of different ages are compared at one time.

**crowd** A larger group structure than a clique that is usually based on reputation; members may or may not spend much time together.

**crystallized intelligence** Accumulated information and verbal skills, which increase in middle adulthood, according to Horn.

**cultural-familial intellectual disability**

Condition in which there is no evidence of organic brain damage but the individual's IQ generally is between 50 and 70.

**culture** The behavior patterns, beliefs, and all other products of a group that are passed on from generation to generation.

**culture-fair tests** Tests of intelligence that are designed to be free of cultural bias.

## D

**date or acquaintance rape** Coercive sexual activity directed at someone with whom the perpetrator is at least casually acquainted.

**deferred imitation** Imitation that occurs after a delay of hours or days.

**dementia** A global term for any neurological disorder in which the primary symptoms involve a deterioration of mental functioning.

**denial and isolation** Kübler-Ross' first stage of dying, in which the dying person denies that she or he is really going to die.

**depression** Kübler-Ross' fourth stage of dying, in which the dying person comes to accept the certainty of her or his death. A period of depression or preparatory grief may appear.

**descriptive research** Studies designed to observe and record behavior.

**development** The pattern of change that begins at conception and continues through the life span. Most development involves growth, although it also includes decline brought on by aging and dying.

**developmental cascade model** Involves connections across domains over time that influence developmental pathways and outcomes.

**developmental quotient (DQ)** An overall score that combines subscores in motor, language, adaptive, and personal-social domains in the Gesell assessment of infants.

**developmentally appropriate practice (DAP)**

Education that focuses on the typical developmental patterns of children (age-appropriateness) and the uniqueness of each child (individual-appropriateness).

**difficult child** A child who tends to react negatively and cry frequently, engages in irregular daily routines, and is slow to accept change.

**direct instruction approach** A structured, teacher-centered educational approach that is characterized by teacher direction and control, mastery of academic skills, high expectations for students' progress, maximum time spent on learning tasks, and efforts to keep negative affect to a minimum.

**dishabituation** Recovery of a habituated response after a change in stimulation.

**divergent thinking** Thinking that produces many answers to the same question and is characteristic of creativity.

**divided attention** Concentrating on more than one activity at the same time.

**DNA** A complex molecule that contains genetic information.

**domain theory of moral development**

Theory that identifies different domains of social knowledge and reasoning, including moral, social conventional, and personal domains. These domains arise from children's and adolescents' attempts to understand and deal with different forms of social experience.

**doula** A caregiver who provides continuous physical, emotional, and educational support for the mother before, during, and after childbirth.

**Down syndrome** A form of intellectual disability that is caused by the presence of an extra copy of chromosome 21.

**dual-process model** A model of coping with bereavement that emphasizes oscillation between two dimensions: (1) loss-oriented stressors, and (2) restoration-oriented stressors.

**dynamic systems theory** The perspective on motor development that seeks to explain how motor behaviors are assembled for perceiving and acting.

**dyscalculia** Also known as developmental arithmetic disorder; a learning disability that involves difficulty in math computation.

**dysgraphia** A learning disability that involves difficulty in handwriting.

**dyslexia** A category of learning disabilities involving a severe impairment in the ability to read and spell.

## E

**easy child** A child who is generally in a positive mood, quickly establishes regular routines in infancy, and adapts easily to new experiences.

**eclectic theoretical orientation** An orientation that does not follow any one theoretical approach but rather selects from each theory whatever is considered the best in it.

**ecological view** The view that perception functions to bring organisms in contact with the environment and to increase adaptation.

**egocentrism** The inability to distinguish between one's own perspective and someone else's (salient feature of the first substage of preoperational thought).

**elaboration** An important strategy for remembering that involves engaging in more extensive processing of information.

**eldercare** Physical and emotional caretaking for older members of the family, whether by giving day-to-day physical assistance or by being responsible for overseeing such care.

**embryonic period** The period of prenatal development that occurs two to eight weeks after conception. During the embryonic period, the rate of cell differentiation intensifies, support systems for the cells form, and organs appear.

**emerging adulthood** The transition from adolescence to adulthood (occurring from

approximately 18 to 25 years of age), which is characterized by experimentation and exploration.

**emotion** Feeling, or affect, that occurs when a person is in a state or interaction that is important to him or her. Emotion is characterized by behavior that reflects (expresses) the pleasantness or unpleasantness of the state a person is in or the transactions being experienced.

**emotional and behavioral disorders**

Serious, persistent problems that involve relationships, aggression, depression, fears associated with personal or school matters, as well as other inappropriate socioemotional characteristics.

**empty nest syndrome** A decrease in marital satisfaction that occurs after children leave home, because parents derive considerable satisfaction from their children.

**epigenetic view** Emphasizes that development is the result of an ongoing, bidirectional interchange between heredity and environment.

**episodic memory** The retention of information about the details of life's happenings.

**equilibration** A mechanism that Piaget proposed to explain how children shift from one stage of thought to the next.

**erectile dysfunction (ED)** The inability to adequately achieve and maintain an erection to attain satisfactory sexual performance.

**Erikson's theory** Includes eight stages of human development. Each stage consists of a unique developmental task that confronts individuals with a crisis that must be resolved.

**ethnic gloss** Using an ethnic label such as *African American* or *Latino* in a superficial way that portrays an ethnic group as being more homogeneous than it really is.

**ethnic identity** An enduring, basic aspect of the self that includes a sense of membership in an ethnic group and the attitudes and feelings related to that membership.

**ethnicity** A characteristic based on cultural heritage, nationality characteristics, race, religion, and language.

**ethology** Stresses that behavior is strongly influenced by biology, is tied to evolution, and is characterized by critical or sensitive periods.

**euthanasia** The act of painlessly ending the lives of persons who are suffering from incurable diseases or severe disabilities; sometimes called "mercy killing." In euthanasia, the physician or a third party administers the lethal medication (active euthanasia) or withdraws life-sustaining treatments.

**evocative genotype-environment correlations**

Correlations that exist when the child's genetically influenced characteristics elicit certain types of environments.

**evolutionary psychology** Emphasizes the importance of adaptation, reproduction, and "survival of the fittest" in shaping behavior.

**evolutionary theory of aging** This theory states that natural selection has not eliminated many harmful conditions and nonadaptive characteristics

in older adults; thus, the benefits conferred by evolution decline with age because natural selection is linked to reproductive fitness.

**executive attention** Aspects of thinking that include planning actions, allocating attention to goals, detecting and compensating for errors, monitoring progress on tasks, and dealing with novel or difficult circumstances.

**executive function** An umbrella-like concept that consists of a number of higher-level cognitive processes linked to the development of the brain's prefrontal cortex. Executive function involves managing one's thoughts to engage in goal-directed behavior and to exercise self-control.

**experiment** A carefully regulated procedure in which one or more of the factors believed to influence the behavior being studied are manipulated while all other factors are held constant.

**explicit memory** Memory of facts and experiences that individuals consciously know and can state.

## F

**fast mapping** A process that helps to explain how young children learn the connection between a word and its referent so quickly.

**fertilization** A stage in reproduction when an egg and a sperm fuse to create a single cell, called a zygote.

**fetal alcohol spectrum disorders (FASD)** A cluster of abnormalities that appear in the offspring of some mothers who drink alcohol heavily during pregnancy.

**fetal period** Lasting about seven months, the prenatal period between two months after conception and birth in typical pregnancies.

**fight-or-flight** The view that when men experience stress, they are more likely to engage in a fight-or-flight pattern, as reflected in being aggressive, withdrawing from social contact, or drinking alcohol.

**fine motor skills** Motor skills that involve more finely tuned movements, such as finger dexterity.

### first habits and primary circular reactions

Piaget's second sensorimotor substage, which develops between 1 and 4 months of age. In this substage, the infant coordinates sensation and two types of schemes: habits and primary circular reactions.

**fluid intelligence** The ability to reason abstractly, which begins to decline from middle adulthood onward, according to Horn.

**fragile X syndrome** A genetic disorder involving an abnormality in the X chromosome, which becomes constricted and often breaks.

**free-radical theory** A microbiological theory of aging that states that people age because normal metabolic processes within their cells produce unstable oxygen molecules known as free radicals. These molecules ricochet around inside cells, damaging DNA and other cellular structures.

**fuzzy trace theory** States that memory is best understood by considering two types of memory

representations: (1) verbatim memory trace, and (2) gist. In this theory, older children's better memory is attributed to the fuzzy traces created by extracting the gist of information.

### fuzzy-trace theory dual-process model

States that decision making is influenced by two systems—"verbatim" analytical (literal and precise) and gist-based intuition (simple bottom-line meaning)—which operate in parallel; in this model, gist-based intuition benefits adolescent decision making more than analytical thinking does.

## G

**games** Activities engaged in for pleasure that include rules and often involve competition with one or more individuals.

**gender identity** The sense of being male or female, which most children acquire by the time they are 3 years old.

**gender role** A set of expectations that prescribes how females or males should think, act, and feel.

**gender schema theory** The theory that gender typing emerges as children develop gender schemas of their culture's gender-appropriate and gender-inappropriate behavior.

**gender** The characteristics of people as males or females.

**gender stereotypes** Broad categories that reflect our impressions and beliefs about females and males.

**gender typing** Acquisition of a traditional masculine or feminine role.

**gene × environment (G × E) interaction** The interaction of a specific measured variation in the DNA and a specific measured aspect of the environment.

**generational inequity** The view that our aging society is being unfair to its younger members because older adults pile up advantages by receiving inequitably large allocations of resources.

**genes** Units of hereditary information composed of DNA. Genes help cells to reproduce themselves and help manufacture the proteins that maintain life.

**genotype** A person's genetic heritage; the actual genetic material.

**germinal period** The period of prenatal development that takes place in the first two weeks after conception. It includes the creation of the zygote, continued cell division, and the attachment of the zygote to the uterine wall.

**gifted** Having above-average intelligence (an IQ of 130 or higher) and/or superior talent for something.

**glaucoma** Damage to the optic nerve because of the pressure created by a buildup of fluid in the eye.

**goodness of fit** Refers to the match between a child's temperament and the environmental demands with which the child must cope.

**grasping reflex** A neonatal reflex that occurs when something touches the infant's palms and the infant responds by grasping tightly.

**grief** The emotional numbness, disbelief, separation anxiety, despair, sadness, and loneliness that accompany the loss of someone we love.

**gross motor skills** Motor skills that involve large-muscle activities, such as walking.

**growth hormone deficiency** Absence or deficiency of growth hormone produced by the pituitary gland to stimulate the body to grow.

## H

**habituation** Decreased responsiveness to a stimulus after repeated presentations of the stimulus.

**heteronomous morality** The first stage of moral development in Piaget's theory, occurring from approximately 4 to 7 years of age. Justice and rules are conceived of as unchangeable properties of the world, removed from the control of people.

**hormonal stress theory** The theory that aging in the body's hormonal system can decrease resistance to stress and increase the likelihood of disease.

**hormones** Powerful chemical substances secreted by the endocrine glands and carried through the body by the bloodstream.

**hospice** A program committed to making the end of life as free from pain, anxiety, and depression as possible. The goals of hospice contrast with those of a hospital, which are to cure disease and prolong life.

**hypotheses** Specific assumptions and predictions that can be tested to determine their accuracy.

**hypothetical-deductive reasoning** Piaget's formal operational concept that adolescents have the cognitive ability to develop hypotheses, or best guesses, about ways to solve problems.

## I

**identity achievement** Marcia's term for the status of individuals who have undergone a crisis and have made a commitment.

**identity diffusion** Marcia's term for the status of individuals who have not yet experienced a crisis (explored meaningful alternatives) or made any commitments.

**identity foreclosure** Marcia's term for the status of individuals who have made a commitment but have not experienced a crisis.

**identity moratorium** Marcia's term for the status of individuals who are in the midst of a crisis, but their commitments are either absent or vaguely defined.

**imaginary audience** Adolescents' belief that others are as interested in them as they themselves are, as well as attention-getting behavior motivated by a desire to be noticed, visible, and "on stage."

**immanent justice** The concept that if a rule is broken, punishment will be meted out immediately.

**implicit memory** Memory without conscious recollection; involves skills and routine procedures that are automatically performed.

**inclusion** Educating a child with special requirements full-time in the regular classroom.

**individual differences** The stable, consistent ways in which people differ from each other.

**individualized education plan (IEP)** A written statement that spells out a program specifically tailored to a child with a disability.

**indulgent parenting** A style of parenting in which parents are highly involved with their children but place few demands or controls on them. Indulgent parenting is associated with children's social incompetence, especially a lack of self-control.

**infinite generativity** The ability to produce and comprehend an endless number of meaningful sentences using a finite set of words and rules.

**information-processing theory** Emphasizes that individuals manipulate information, monitor it, and strategize about it. Central to this theory are the processes of memory and thinking.

**insecure avoidant babies** Babies who show insecurity by avoiding the caregiver.

**insecure disorganized babies** Babies who show insecurity by being disorganized and disoriented.

**insecure resistant babies** Babies who often cling to the caregiver, then resist the caregiver by fighting against the closeness, perhaps by kicking or pushing away.

**integrity versus despair** Erikson's eighth and final stage of development, which individuals experience in late adulthood. This involves reflecting on the past and either piecing together a positive review or concluding that one's life has not been well spent.

**intellectual disability** A condition of limited mental ability in which the individual (1) has a low IQ, usually below 70 on a traditional intelligence test, (2) has difficulty adapting to the demands of everyday life, and (3) first exhibits these characteristics by age 18.

**intelligence** Problem-solving skills and the ability to learn from and adapt to the experiences of everyday life.

**intelligence quotient (IQ)** A person's mental age divided by chronological age, multiplied by 100.

**intermodal perception** The ability to relate and integrate information from two or more sensory modalities, such as vision and hearing.

**internalization of schemes** Piaget's sixth and final sensorimotor substage, which develops between 18 and 24 months of age. In this substage, the infant develops the ability to use primitive symbols.

**intimacy in friendships** Self-disclosure and the sharing of private thoughts.

**intuitive thought substage** Piaget's second substage of preoperational thought, in which children begin to use primitive reasoning and want to know the answers to all sorts of questions (between 4 and 7 years of age).

## J

**joint attention** Process that occurs when individuals focus on the same object and are able to track another's behavior, one individual directs another's attention, and reciprocal interaction takes place.

**justice perspective** A moral perspective that focuses on the rights of the individual and in which individuals independently make moral decisions.

**juvenile delinquent** An adolescent who breaks the law or engages in behavior that is considered illegal.

## K

**kangaroo care** Treatment for preterm infants that involves skin-to-skin contact.

**Klinefelter syndrome** A chromosomal disorder in which males have an extra X chromosome, making them XXY instead of XY.

## L

**laboratory** A controlled setting in which many of the complex factors of the "real world" are removed.

**language** A form of communication, whether spoken, written, or signed, that is based on a system of symbols. Language consists of the words used by a community and the rules for varying and combining them.

**language acquisition device (LAD)** Chomsky's term that describes a biological endowment enabling the child to detect the features and rules of language, including phonology, syntax, and semantics.

**lateralization** Specialization of function in one hemisphere of the cerebral cortex or the other.

**learning disability** Difficulty in understanding or using spoken or written language or in doing mathematics. To be classified as a learning disability, the learning problem is not primarily the result of visual, hearing, or motor disabilities; intellectual disability; emotional disorders; or due to environmental, cultural, or economic disadvantage.

**least restrictive environment (LRE)** A setting that is as similar as possible to the one in which children who do not have a disability are educated.

**leisure** The pleasant times after work when individuals are free to pursue activities and interests of their own choosing.

**life expectancy** The number of years that will probably be lived by the average person born in a particular year.

**life span** The maximum number of years an individual can live. The life span of human beings is about 120 to 125 years of age.

**life-span perspective** The perspective that development is lifelong, multidimensional, multidirectional, plastic, multidisciplinary, and contextual; involves growth, maintenance, and regulation; and is constructed through biological, sociocultural, and individual factors working together.

**limbic system** The part of the brain where emotions and rewards are processed.

**long-term memory** A relatively permanent type of memory that holds huge amounts of information for a long period of time.

**longitudinal approach** A research strategy in which the same individuals are studied over a period of time, usually several years or more.

**low birth weight infants** An infant that weighs less than 5 pounds 8 ounces at birth.

## M

**macular degeneration** A disease that involves deterioration of the macula of the retina, which corresponds to the focal center of the visual field.

**major depression** A mood disorder in which the individual is deeply unhappy, demoralized, self-derogatory, and bored. The person does not feel well, loses stamina easily, has poor appetite, and is listless and unmotivated. Major depression is so widespread that it has been called the "common cold" of mental disorders.

**matching hypothesis** Theory that although we prefer a more attractive person in the abstract, in the real world we end up choosing someone who is close to our own level of attractiveness.

**meaning-making coping** Involves drawing on beliefs, values, and goals to change the meaning of a stressful situation, especially in times of chronic stress such as when a loved one dies.

**meiosis** A specialized form of cell division that occurs to form eggs and sperm (also known as gametes).

**memory** A central feature of cognitive development, pertaining to all situations in which an individual retains information over time.

**menarche** A girl's first menstruation.

**menopause** Cessation of a woman's menstrual periods, usually during the late forties or early fifties.

**mental age (MA)** Binet's measure of an individual's level of mental development compared with that of others.

**metabolic syndrome** A condition characterized by hypertension, obesity, and insulin resistance. Metabolic syndrome often leads to the onset of diabetes and cardiovascular disease.

**metacognition** Cognition about cognition, or knowing about knowing.

**metalinguistic awareness** Knowledge about language, such as understanding what a preposition is or being able to discuss the sounds of a language.

**middle adulthood** The developmental period that begins at approximately 40 to 45 years of age and extends to about 60 to 65 years of age.

**mindfulness** Being alert, mentally present, and cognitively flexible while going through life's everyday activities and tasks.

**mindset** The cognitive view, either fixed or growth, that individuals develop for themselves.

**mitochondrial theory** The theory that aging is caused by the decay of mitochondria, tiny cellular bodies that supply energy for function, growth, and repair.

**mitosis** Cellular reproduction in which the cell's nucleus duplicates itself with two new cells being formed, each containing the same DNA as the parent cell, arranged in the same 23 pairs of chromosomes.

**Montessori approach** An educational philosophy in which children are given considerable freedom and

spontaneity in choosing activities and are allowed to move from one activity to another as they desire.

**moral development** Development that involves thoughts, feelings, and behaviors regarding rules and conventions about what people should do in their interactions with other people.

**Moro reflex** A neonatal startle response in which the newborn arches its back, throws its head back, flings out its arms and legs, and then pulls its arms and legs close to the center of the body.

**morphology** Units of meaning involved in word formation.

**mTOR pathway** A cellular pathway involving the regulation of growth and metabolism that has been proposed as a key aspect of longevity.

**myelination** The process by which the nerve cells are covered and insulated with a layer of fat cells, which increases the speed at which information travels through the nervous system.

## N

**narcissism** A self-centered and self-concerned approach toward others.

**natural childbirth** This method of childbirth attempts to reduce the mother's pain by decreasing her fear through information about childbirth and instruction in relaxation techniques to reduce pain during delivery.

**naturalistic observation** Studies that involve observing behavior in real-world settings.

**nature-nurture issue** Debate about whether development is primarily influenced by nature or nurture. Nature refers to an organism's biological inheritance, nurture to its environmental experiences.

**neglected children** Children who are infrequently nominated as a best friend but are not disliked by their peers.

**neglectful parenting** A style of parenting in which the parent is uninvolved in the child's life; this style is associated with children's social incompetence, especially a lack of self-control.

**neo-Piagetians** Developmentalists who argue that Piaget got some things right but that his theory needs considerable revision. They have elaborated on Piaget's theory, giving more emphasis to information processing, strategies, and precise cognitive steps.

### Neonatal Intensive Care Unit

**Neurobehavioral Scale (NNNS)** An "offspring" of the NBAS, the NNNS provides an assessment of the newborn's behavior, neurological and stress responses, and regulatory capacities.

**neuroconstructivist view** A belief that biological processes and environmental conditions influence the brain's development; the brain has plasticity and is context dependent; and development of the brain and cognitive development are closely linked.

**neurogenesis** The generation of new neurons.

**neurons** Nerve cells that handle information processing at the cellular level in the brain.

**nonnormative life events** Unusual occurrences that have a major impact on an individual's life.

**normal distribution** A symmetrical distribution with most scores falling in the middle of the possible range of scores and a few scores appearing toward the extremes of the range.

**normative age-graded influences** Influences that are similar for individuals in a particular age group.

### normative history-graded influences

Influences that are common to people of a particular generation because of historical circumstances.

## O

**object permanence** The Piagetian term for understanding that objects and events continue to exist even when they cannot directly be seen, heard, or touched.

**operations** In Piaget's theory, these are reversible mental actions that allow children to do mentally what they formerly did physically.

**organic intellectual disability** A genetic disorder or condition involving brain damage that is linked to a low level of intellectual functioning.

**organization** Piaget's concept of grouping isolated behaviors and thoughts into a higher-order, more smoothly functioning cognitive system.

**organogenesis** Organ formation that takes place during the first two months of prenatal development.

**osteoporosis** A chronic condition that involves an extensive loss of bone tissue and is the main reason many older adults walk with a marked stoop.

## P

**pain cry** A sudden appearance of a long, initial loud cry without preliminary moaning, followed by breath holding.

**palliative care** The type of care emphasized in a hospice, which involves reducing pain and suffering and helping individuals die with dignity.

**Parkinson disease** A chronic, progressive disease characterized by muscle tremors, slowing of movement, and partial facial paralysis.

**passive euthanasia** The withholding of available treatments, such as life-sustaining devices, in order to allow a person to die.

### passive genotype-environment

**correlations** Correlations that exist when the natural parents, who are genetically related to the child, provide a rearing environment for the child.

**perception** The interpretation of what is sensed.

**personal fable** The part of adolescent egocentrism that involves an adolescent's sense of uniqueness and invincibility (or invulnerability).

**perspective taking** The social cognitive process involved in assuming the perspective of others and understanding their thoughts and feelings.

**phenotype** The way an individual's genotype is expressed in observed and measurable characteristics.

**phenylketonuria (PKU)** A genetic disorder in which an individual cannot properly metabolize an

amino acid called phenylalanine. PKU is now easily detected but, if left untreated, results in intellectual disability and hyperactivity.

**phonics approach** The idea that reading instruction should teach the basic rules for translating written symbols into sounds.

**phonology** The sound system of the language, including the sounds that are used and how they may be combined.

**Piaget's theory** Theory stating that children actively construct their understanding of the world and go through four stages of cognitive development.

**placenta** A prenatal life-support system that consists of a disk-shaped group of tissues in which small blood vessels from the mother and offspring intertwine.

**popular children** Children who are frequently nominated as a best friend and are rarely disliked by their peers.

**postconventional reasoning** The highest level in Kohlberg's theory of moral development. At this level, the individual recognizes alternative moral courses, explores the options, and then decides on a personal moral code.

**postformal thought** Thinking that is reflective, relativistic, contextual, provisional, realistic, and influenced by emotions.

**postpartum depression** A condition experienced by women who have such strong feelings of sadness, anxiety, or despair that they have trouble coping with daily tasks during the postpartum period.

**postpartum period** The period after childbirth when the mother adjusts, both physically and psychologically, to the process of childbirth. This period lasts for about six weeks or until her body has completed its adjustment and returned to a near prepregnant state.

**practice play** Play that involves repetition of behavior when new skills are being learned or when physical or mental mastery and coordination of skills are required for games or sports.

**pragmatics** The appropriate use of language in different contexts.

**preconventional reasoning** The lowest level in Kohlberg's theory of moral development. The individual's moral reasoning is controlled primarily by external rewards and punishment.

**preoperational stage** Piaget's second stage, lasting from about 2 to 7 years of age, during which children begin to represent the world with words, images, and drawings, and symbolic thought goes beyond simple connections of sensory information and physical action; stable concepts are formed, mental reasoning emerges, egocentrism is present, and magical beliefs are constructed.

**prepared childbirth** Developed by French obstetrician Ferdinand Lamaze, this childbirth strategy is similar to natural childbirth but includes a special breathing technique to control pushing in the final stages of labor and a more detailed anatomy and physiology course.

**pretense/symbolic play** Play in which the child transforms the physical environment into a symbol.

**preterm infants** Those born before the completion of 37 weeks of gestation (the time between fertilization and birth).

**primary circular reaction** A scheme based on the attempt to reproduce an event that initially occurred by chance.

**primary emotions** Emotions that are present in humans and other animals and emerge early in life; examples are joy, anger, sadness, fear, and disgust.

**Project Head Start** A government-funded program that is designed to provide children from low-income families with the opportunity to acquire the skills and experiences important for school success.

**prolonged grief disorder** Grief that involves enduring despair and remains unresolved over an extended period of time.

**prospective memory** Remembering to do something in the future.

**proximodistal pattern** Developmental sequence in which growth starts at the center of the body and moves toward the extremities.

**psychoanalytic theories** Theories that describe development as primarily unconscious and heavily colored by emotion. Behavior is merely a surface characteristic, and the symbolic workings of the mind have to be analyzed to understand behavior. Early experiences with parents are emphasized.

**psychoanalytic theory of gender** A theory deriving from Freud's view that the preschool child develops a sexual attraction to the opposite-sex parent, by approximately 5 or 6 years of age renounces this attraction because of anxious feelings, and subsequently identifies with the same-sex parent, unconsciously adopting the same-sex parent's characteristics.

**puberty** A period of rapid physical maturation, occurring primarily in early adolescence, that involves hormonal and bodily changes.

## R

**rape** Forcible sexual intercourse with a person who does not consent to it.

**rappor talk** The language of conversation; it is the way of establishing connections and negotiating relationships.

**reciprocal socialization** Socialization that is bidirectional; children socialize parents, just as parents socialize children.

**reflexes** Built-in reactions to stimuli that govern the newborn's movements, which are automatic and beyond the newborn's control.

**reflexive smile** A smile that does not occur in response to external stimuli. It happens during the first month after birth, usually during sleep.

**rejected children** Children who are infrequently nominated as a best friend and are actively disliked by their peers.

**religion** An organized set of beliefs, practices, rituals, and symbols that increases an individual's connection to a sacred or transcendent other (God, higher power, or higher truth).

**religiousness** The degree to which an individual is affiliated with an organized religion, participates in prescribed rituals and practices, feels a sense of connection with its beliefs, and is involved in a community of believers.

**report talk** Talk that is designed to give information; this category of communication includes public speaking.

**rite of passage** A ceremony or ritual that marks an individual's transition from one status to another. Most rites of passage focus on the transition to adult status.

**romantic love** Also called passionate love or *eros*, romantic love has strong sexual and infatuation components and often predominates early in a love relationship.

**rooting reflex** A newborn's built-in reaction that occurs when the infant's cheek is stroked or the side of the mouth is touched. In response, the infant turns his or her head toward the side that was touched, in an apparent effort to find something to suck.

## S

**scaffolding** Practice in which parents time interactions so that infants experience turn taking with the parents; these interactions allow infants to be more skillful than they would be if they had to rely only on their own abilities.

**schemes** In Piaget's theory, actions or mental representations that organize knowledge.

**scientific method** An approach that can be used to obtain accurate information. It includes the following steps: (1) conceptualize the problem, (2) collect data, (3) draw conclusions, and (4) revise research conclusions and theory.

**secondary circular reactions** Piaget's third sensorimotor substage, which develops between 4 and 8 months of age. In this substage, the infant becomes more object-oriented, moving beyond preoccupation with the self.

**secure attachment style** An attachment style that describes adults who have positive views of relationships, find it easy to get close to others, and are not overly concerned or stressed out about their romantic relationships.

**securely attached babies** Babies who use the caregiver as a secure base from which to explore the environment.

**selective attention** Focusing on a specific aspect of experience that is relevant while ignoring others that are irrelevant.

**selective optimization with compensation theory** The theory that successful aging is related to three main factors: selection, optimization, and compensation.

**self-concept** Domain-specific evaluations of the self.

**self-conscious emotions** Emotions that require self-awareness, especially consciousness and a sense of "me"; examples include jealousy, empathy, and embarrassment.

**self-efficacy** The belief that one can master a situation and produce favorable outcomes.

**self-esteem** The global evaluative dimension of the self. Self-esteem is also referred to as self-worth or self-image.

**self-understanding** The child's cognitive representation of self, the substance and content of the child's self-conceptions.

**semantic memory** A person's knowledge about the world—including one's fields of expertise, general academic knowledge of the sort learned in school, and "everyday knowledge."

**semantics** The meaning of words and sentences.

**sensation** The product of the interaction between information and the sensory receptors—the eyes, ears, tongue, nostrils, and skin.

**sensorimotor play** Behavior engaged in by infants that lets them derive pleasure from exercising their existing sensorimotor schemas.

**sensorimotor stage** The first of Piaget's stages, which lasts from birth to about 2 years of age; infants construct an understanding of the world by coordinating sensory experiences with motoric actions.

**separation protest** An infant's distressed crying when the caregiver leaves.

**seriation** The concrete operation that involves ordering stimuli along a quantitative dimension (such as length).

**service learning** A form of education that promotes social responsibility and service to the community.

### sexually transmitted infections (STIs)

Infections that are contracted primarily through sexual contact, including oral-genital and anal-genital contact.

**shape constancy** The recognition that an object's shape remains the same even though its orientation to the observer changes.

**short-term memory** The memory component in which individuals retain information for up to 30 seconds, assuming there is no rehearsal of the information.

**sickle-cell anemia** A genetic disorder that affects the red blood cells and occurs most often in people of African descent.

**simple reflexes** Piaget's first sensorimotor substage, which corresponds to the first month after birth. In this substage, sensation and action are coordinated primarily through reflexive behaviors.

**sirtuins** A family of proteins that have been proposed as having important influences on longevity, mitochondria functioning in energy, calorie restriction benefits, stress resistance, and cardiovascular functioning.

**size constancy** The recognition that an object remains the same even though the retinal image of the object changes as the observer moves toward or away from the object.

**slow-to-warm-up child** A child who has a low activity level, is somewhat negative, and displays a low intensity of mood.

**small for date infants** Also called small for gestational age infants, these infants' birth weights are below normal when the length of pregnancy is considered. Small for date infants may be preterm or full term.

**social clock** The timetable according to which individuals are expected to accomplish life's tasks, such as getting married, having children, or establishing themselves in a career.

**social cognitive theory** The view of psychologists who emphasize behavior, environment, and cognition as the key factors in development.

**social cognitive theory of gender** A theory emphasizing that children's gender development occurs through the observation and imitation of gender behavior and through the rewards and punishments children experience for gender-appropriate and gender-inappropriate behavior.

**social constructivist approach** An approach that emphasizes the social contexts of learning and asserts that knowledge is mutually built and constructed. Vygotsky's theory reflects this approach.

**social conventional reasoning** Thoughts about social consensus and convention, in contrast with moral reasoning, which stresses ethical issues.

**social play** Play that involves social interactions with peers.

**social policy** A national government's course of action designed to promote the welfare of its citizens.

**social referencing** "Reading" emotional cues in others to help determine how to act in a particular situation.

**social role theory** A theory that gender differences result from the contrasting roles of men and women.

**social smile** A smile in response to an external stimulus, which early in development is typically a face.

**socioeconomic status (SES)** Refers to the grouping of people with similar occupational, educational, and economic characteristics.

**socioemotional processes** Changes in an individual's interpersonal relationships, emotions, and personality.

**socioemotional selectivity theory** The theory that older adults become more selective about their social networks. Because they place a high value on emotional satisfaction, older adults often spend more time with familiar individuals with whom they have had rewarding relationships.

**source memory** The ability to remember where one learned something.

**spirituality** Experiencing something beyond oneself in a transcendent manner and living in a way that benefits others and society.

**stability-change issue** Debate about whether we become older renditions of our early experience (stability) or whether we develop into someone different from who we were at an earlier point in development (change).

**standardized test** A test with uniform procedures for administration and scoring. Many standardized tests allow a person's performance to be compared with the performance of other individuals.

**stereotype threat** The anxiety that one's behavior might confirm a negative stereotype about one's group.

**Strange Situation** An observational measure of infant attachment that requires the infant to move through a series of introductions, separations, and reunions with the caregiver and an adult stranger in a prescribed order.

**stranger anxiety** An infant's fear and wariness of strangers; it tends to appear during the second half of the first year of life.

**strategies** Deliberate mental activities that improve the processing of information.

**sucking reflex** A newborn's built-in reaction to automatically suck an object placed in its mouth. The sucking reflex enables the infant to get nourishment before he or she has associated a nipple with food and also serves as a self-soothing or self-regulating mechanism.

**sudden infant death syndrome (SIDS)** A condition that occurs when an infant stops breathing, usually during the night, and suddenly dies without an apparent cause.

**sustained attention** Focused and extended engagement with an object, task, event, or other aspect of the environment.

**symbolic function substage** Piaget's first substage of preoperational thought, in which the child gains the ability to mentally represent an object that is not present (between about 2 and 4 years of age).

**syntax** The ways words are combined to form acceptable phrases and sentences.

## T

**telegraphic speech** The use of short and precise words without grammatical markers such as articles, auxiliary verbs, and other connectives.

**temperament** Involves individual differences in behavioral styles, emotions, and characteristic ways of responding.

**tend-and-befriend** Taylor's view that when women experience stress, they are likely to engage in a tend-and-befriend pattern, seeking social alliances with others, especially female friends.

**teratogen** From the Greek word *teras*, meaning "monster." Any agent that causes a birth defect. The field of study that investigates the causes of birth defects is called teratology.

**tertiary circular reactions, novelty, and curiosity** Piaget's fifth sensorimotor substage, which develops between 12 and 18 months of age. In this substage, infants become intrigued by the many properties of objects and by the many things that they can make happen to objects.

**theory** An interrelated, coherent set of ideas that helps to explain phenomena and facilitate predictions.

**theory of mind** Awareness of one's own mental processes and the mental processes of others.

**top-dog phenomenon** The circumstance of moving from the top position in elementary school to the lowest position in middle or junior high school.

**transgender** A broad term that refers to individuals who adopt a gender identity that differs from the one assigned to them at birth.

**transitivity** The ability to logically combine relations to understand certain conclusions.

**triarchic theory of intelligence** Sternberg's theory that intelligence consists of analytical intelligence, creative intelligence, and practical intelligence.

**trophoblast** The outer layer of cells that develops in the germinal period. These cells provide nutrition and support for the embryo.

**Turner syndrome** A chromosome disorder in females in which either an X chromosome is missing, making the person XO instead of XX, or the second X chromosome is partially deleted.

**twin study** A study in which the behavioral similarity of identical twins is compared with the behavioral similarity of fraternal twins.

## U

**umbilical cord** Part of the prenatal life-support system that contains two arteries and one vein that connect the baby to the placenta.

## V

**visual preference method** A method used to determine whether infants can distinguish one stimulus from another by measuring the length of time they attend to different stimuli.

**Vygotsky's theory** A sociocultural cognitive theory that emphasizes how culture and social interaction guide cognitive development.

## W

**Wernicke's area** An area in the brain's left hemisphere that is involved in language comprehension.

**whole-language approach** An approach to reading instruction based on the idea that instruction should parallel children's natural language learning. Reading materials should be whole and meaningful.

**wisdom** Expert knowledge about the practical aspects of life that permits excellent judgment about important matters.

**working memory** A mental "workbench" where individuals manipulate and assemble information when making decisions, solving problems, and comprehending written and spoken language.

## X

**XY syndrome** A chromosomal disorder in which males have an extra Y chromosome.

## Z

**zone of proximal development (ZPD)**

Vygotsky's term for tasks that are too difficult for children to master alone but can be mastered with the assistance of adults or more-skilled children.

**zygote** A single cell formed through fertilization.

- Abortion, 63  
Abuse. *See Child maltreatment*  
Academic achievement  
  cross-cultural studies of, 329–332  
  friendship and, 324  
  gender differences in, 315–316  
  parenting and, 325–326, 330, 331  
  role of parents in, 325–326, 331  
  socioeconomic status and,  
    327–328  
Acceptance stage of dying, 615  
Accidents  
  in late adulthood, 536  
  in middle and late childhood, 269  
Accommodation, in infants, 141  
Accountability, of schools, 326–327  
Acquaintance rape, 419  
Active euthanasia, 609  
Active genotype-environment  
  correlations, 68  
Activity theory, 581  
Acupuncture, during childbirth, 93  
Adaptive behavior, 50–51  
Adderall, 274  
Addiction, 410. *See also Substance abuse*  
Adolescents  
  adopted, 65–66  
  attitude toward death in, 613  
  autonomy and attachment  
    in, 378–379  
  brain development in, 344–345  
  cognitive development in, 358–362  
  conflict with parents in, 379–380  
  contraceptive use in, 348  
  culture and, 385–386  
  dating and romantic relationships  
    of, 382–384  
  death in, 354  
  defined, 15  
  depression in, 391–394  
  eating disorders in, 357–358  
  egocentrism in, 359–360  
  emerging adulthood and, 374  
  exercise in, 351–352  
  families and, 385  
  friendship among, 381, 382  
  gender and, 378  
  health issues in, 351–354, 385  
  identity in, 372–375  
  information processing in, 360–362  
  juvenile delinquency and, 390–391  
  nutrition in, 351–352  
  overview of, 339–340  
  parenting of, 377–380, 391  
  peer pressure for, 381–382  
  physical development in, 341–344  
  pregnancy in, 348–350  
  prevention/intervention programs  
    for at-risk, 394–395  
  puberty in, 341–344  
  religious and spiritual development  
    in, 375–377  
  self-esteem in, 371–372  
  service learning for, 366  
  sexual identity in, 345–346  
  sexuality in, 345–350  
  sleep patterns in, 352–354  
  stepfamilies and, 320  
  substance abuse in, 354–356  
  suicide in, 393–394  
  transition to adulthood,  
    402–405  
  in vitro fertilization and  
    developmental outcomes in, 64  
Adoption  
  diversity and, 64–65  
  outcomes for children, 65  
  studies on, 68, 174  
Adoptive parents  
  developmental stages and, 65  
  diversity among, 64–65  
Adult children  
  living with parents, 505  
  with parents in late  
    adulthood, 593–594  
Adulthood. *See also Early adulthood; Emerging adulthood; Late adulthood; Middle adulthood*  
  attention in, 147  
  emerging, 402–405  
  mistreatment as children and, 248  
  stages of, 492–494  
Adult lifestyles  
  cohabiting adults, 444–445  
  divorced adults, 448–449  
  gay and lesbian adults, 449–450  
  in late adulthood, 591–593  
  married adults, 445–448  
  remarried adults, 449  
  single adults, 443–444  
Advance care planning, 608–609
